# Coherent elastic neutrino-nucleus scattering (CE $\nu$ NS)

- NC (flavor-independent) process postulated by D.Z. Freedman [1] / Kopeliovich & Frankfurt [2] in 1974
- In a CE $\nu$ NS interaction, a neutrino scatters off of a nucleus whose nucleons recoil *in phase*, resulting in an enhanced cross section; total cross section scales approximately like  $N^2$

$$\sigma \approx \frac{G_F^2 N^2}{4\pi} E_\nu^2$$

Cross section can be orders of magnitude larger than IBD process used to first observe neutrinos!

# “An act of hubris”

Freedman [1] noted that several factors combine to make CE $\nu$ NS an exceptionally challenging process to observe

- Only evidence of the interaction is a low-energy recoiling nucleus
  - Heavier nuclei: higher cross section but lower recoil energies
  - Nuclear recoil signal yields are quenched, i.e. reduced compared to signal from electrons of same energy by a factor called the quenching factor (QF)
  - Detector performance hard to calibrate
- Very-low-threshold detectors are very sensitive to backgrounds
  - Neutron backgrounds are particularly dangerous: produce low-energy nuclear recoils just like CE $\nu$ NS
- Need an appropriate source of neutrinos

# Physics from CE $\nu$ NS

**Supernova physics** - Could play a role in dynamics of core-collapse SNe [1] and offers potential way to *observe* SNe neutrinos [2]

**Weak mixing angle** - Unique probe of  $Q_W^2$  at a unique  $Q$  in a region sensitive to dark  $Z$  boson models [3]

**Non-standard neutrino interactions** - explicit dependence on non-universal and flavor-changing neutral currents [4]

**Nuclear form factor** - Provides a way to measure neutron distributions using neutrino scattering [5], possibly refining nuclear structure models and informing understanding of neutron star EoS [6]

**Fundamental properties of neutrinos** - sensitivity to effective neutrino charge radius and magnetic moment [7] *and* lift degeneracy of “dark side” solution to  $\theta_{12}$  that would complicate mass-order determination from oscillation experiments [8]

**Neutral-current sterile neutrino search** - all-flavor disappearance experiment [9]

Figure from [8]

# CE $\nu$ NS becomes a background

- Goodman & Witten recognize utility of CE $\nu$ NS-sensitive detectors as potential dark matter detectors [1]
  - DM and CE $\nu$ NS interactions are both coherent scattering processes with the same detectable signature (gently recoiling nuclei)
- Numerous instances of proposed CE $\nu$ NS detectors turning instead into competitive DM searches

P.S. Barbeau, Ph.D. thesis (UChicago 2009)

- Tremendous advances in detector technology to build more sensitive DM searches
- Next generation of WIMP detectors will begin to be sensitive to CE $\nu$ NS from  $^8\text{B}$  solar neutrino flux
  - This “neutrino floor” brings the CE $\nu$ NS and DM relationship full circle

# The Spallation Neutron Source

---

- Located at Oak Ridge National Lab, near Knoxville, TN, USA
- The SNS bombards a liquid mercury target with a  $\sim 1$ -GeV proton beam pulsed at 60 Hz; each beam pulse is  $\sim 700$ -ns wide
  - Power generally  $> 1$  MW - most intense pulsed neutron source in the world!
- Neutrinos are produced by decay of **stopped** pions and muons, resulting in flux with well-defined spectral and timing characteristics
  - Most intense pulsed *neutrino* source in the world!

# The Spallation Neutrino Source

- High-fidelity GEANT4 simulation starts with proton beam; energy spectra very near analytical approximations
- Massive reduction in steady-state backgrounds through timing ( $\mathcal{O}(1000)$ ); facility-wide timing signal can be used to trigger DAQ, both during beam-on and -off periods

# Siting and backgrounds

- Backgrounds depend significantly on siting at SNS
  - Extensive background measurement campaign
- COHERENT experiments located in a ~~basement hallway~~ *neutrino alley*
  - ~8 m.w.e. overburden
  - 20- to 30-m from target
- Primary backgrounds in neutrino alley:
  - Prompt SNS neutrons
  - Neutrino-induced neutrons (NINs)

Approx  $\nu$  flux at CsI[Na] location

$$1e7 \nu / \text{cm}^2 / \text{s} / \text{flavor}$$

# *In situ* measurement of neutron backgrounds

- Prior to CE $\nu$ NS search, neutron detection system installed at location of CsI[Na] detector
- Data informed model of prompt SNS neutron energy distribution
- Established understanding of beam timing w.r.t. SNS timing signal

# *In situ* measurement of neutron backgrounds

# Neutrino-induced neutrons (NINs)

- Dominant background for CEνNS measurement with naïve shielding configuration, but interesting physics of its own
  - Possible role in nucleosynthesis in certain astrophysical environments [1]
  - NIN production on Pb is the fundamental mechanism by which HALO intends to detect supernova neutrinos [2]
  - Process has never before been measured, considerable variation in theoretical predictions (~3x) [3]
- *In situ* measurements give rate limit, plus ongoing measurement of process with “neutrino cubes”

NIN pathways from S.R. Elliott, Phys. Rev. C (2000)

# CE $\nu$ NS with CsI[Na]

*Deployed to SNS in June 2015*

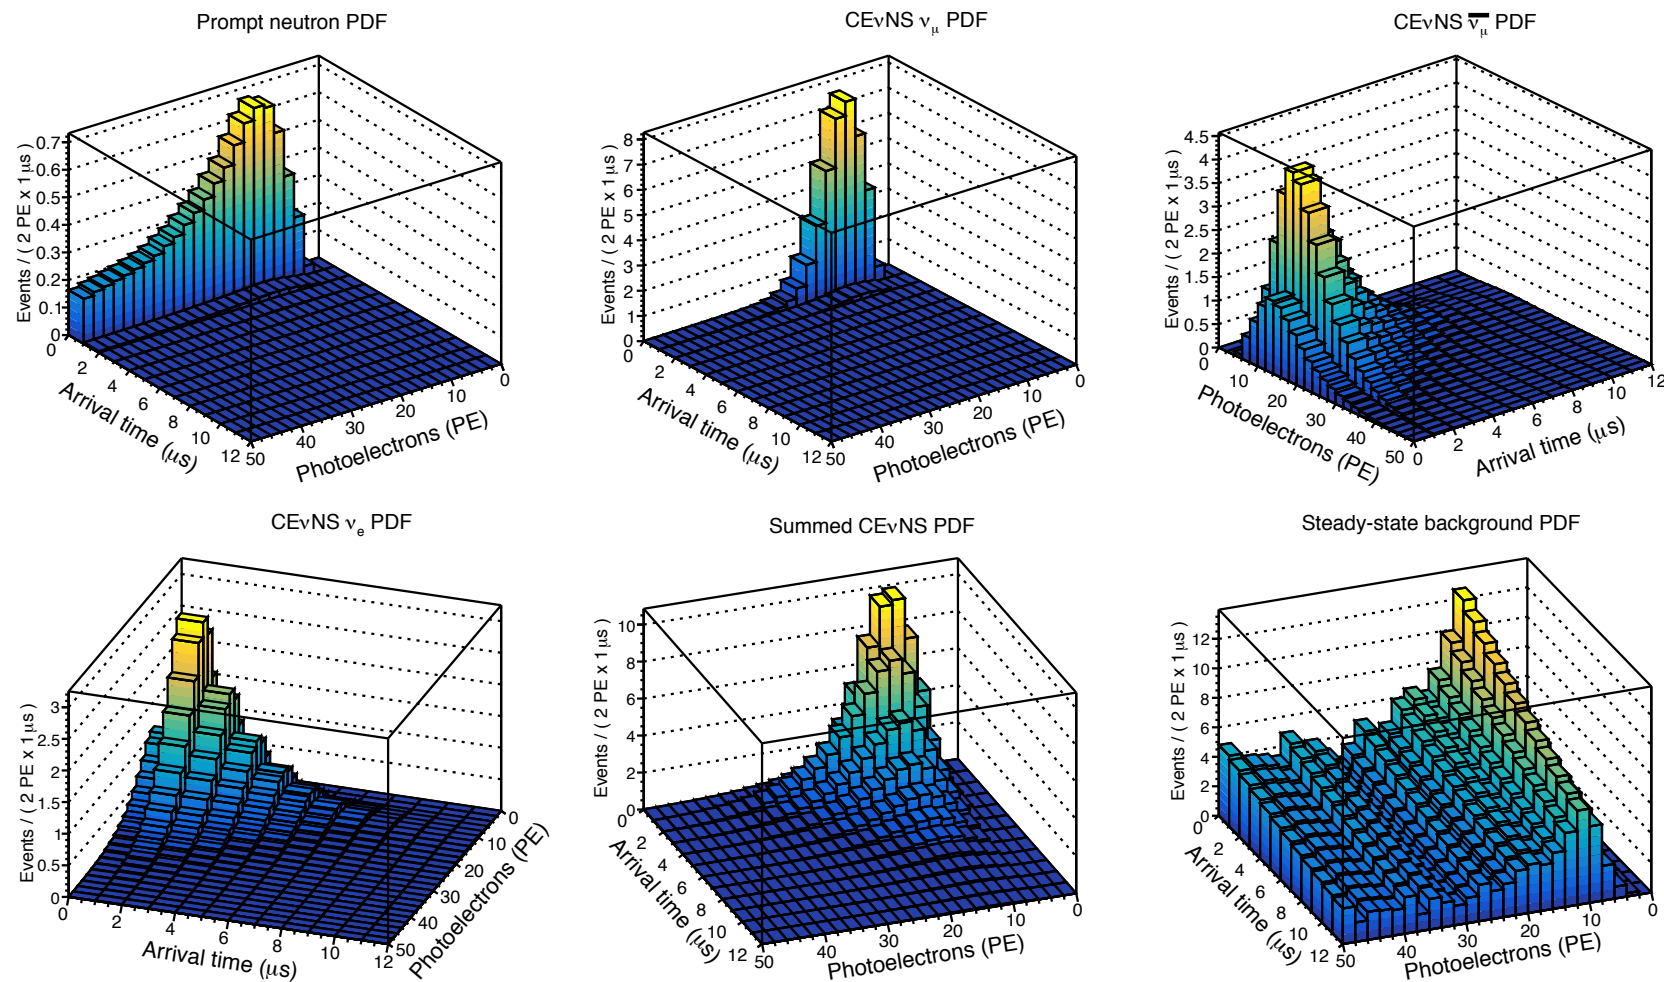

- 14.6-kg crystal made from low-background salts, encased in electroformed-copper can with PTFE reflector and synthetic silica window, surrounded by neutron and gamma shielding, including low-activity lead
- Development led by University of Chicago [1]
- Output of super-bialkali PMT with  $\sim 30\%$  QE digitized for  $70\ \mu\text{s}$ , triggered by SNS timing signal

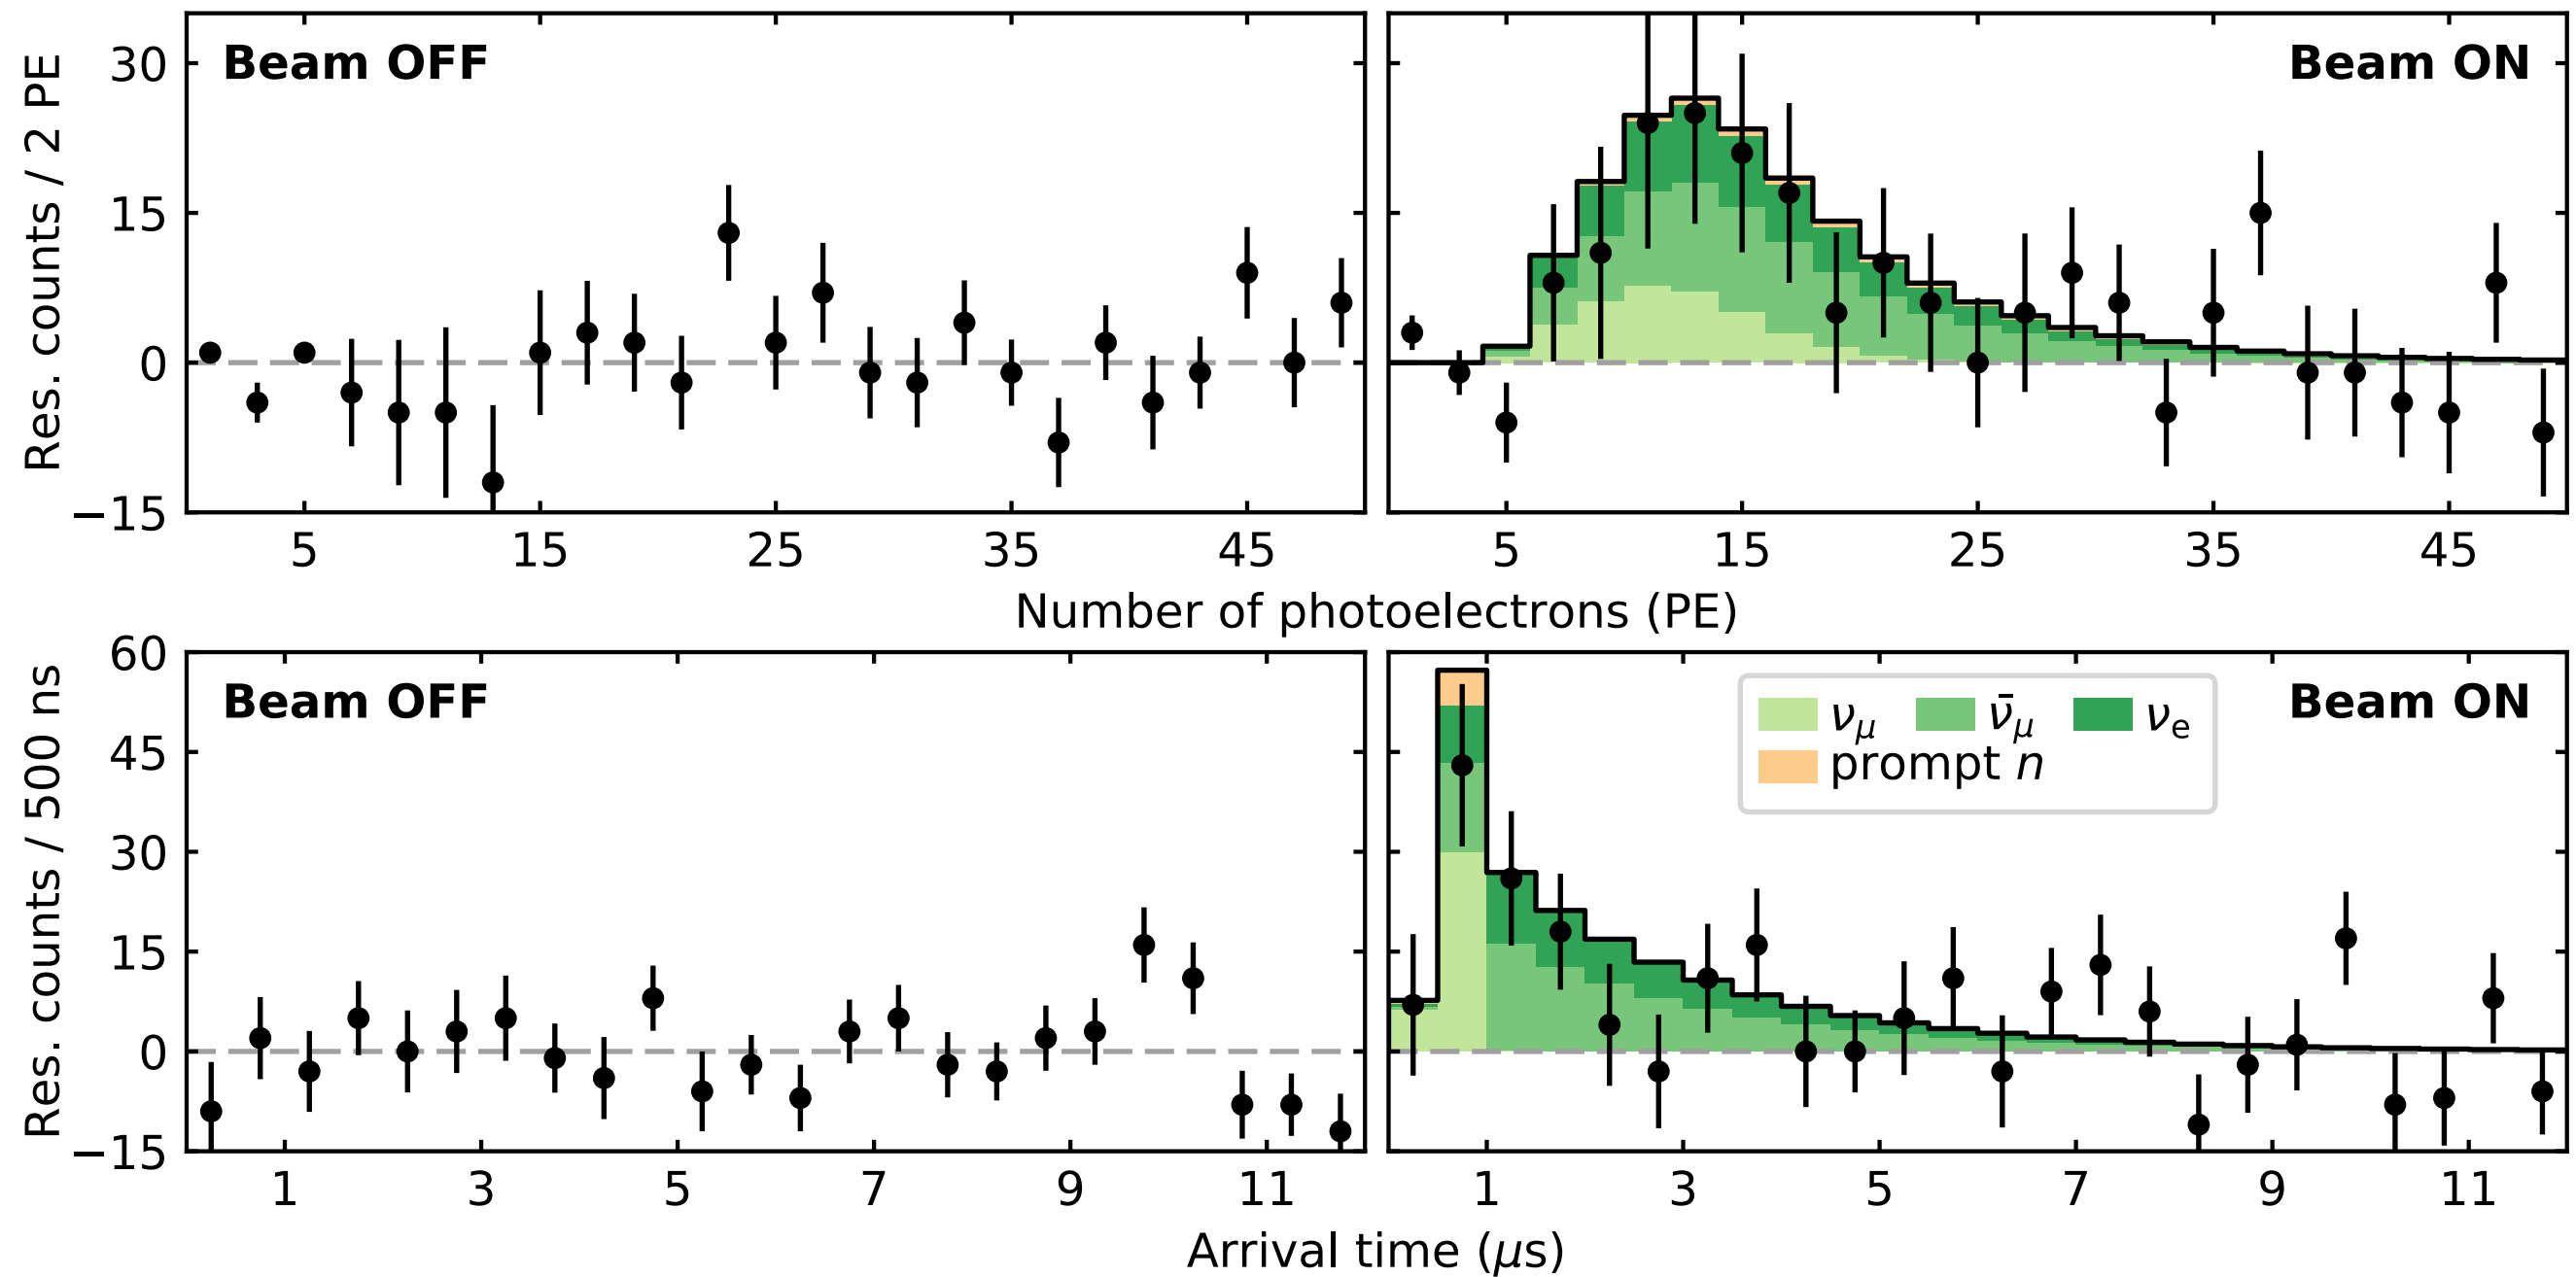

# Rate and shape estimates

- Pulsed nature of beam facilitates analysis in time domain
- 2-D analysis (energy, time) makes use of all available information
- Ultimately performed binned 2-D profile likelihood analysis using PDFs shown here
  - Assumes Standard Model
  - Incorporates knowledge of detector response, analysis acceptance, etc

# SM prediction and data

# Results

- Beam exposure:  $\sim 6$  GWhr, or  $\sim 1.4 \times 10^{23}$  protons on target (0.22 grams of protons)
- Analyzed as a simple counting experiment
  - $136 \pm 31$  counts
- 2-D profile likelihood analysis
  - $134 \pm 22$  counts, within  $1\text{-}\sigma$  of SM prediction of  $173 \pm 48$
  - Null hypothesis disfavored at  $6.7\text{-}\sigma$  level relative to best-fit number of counts
- Able to further constrain some NSI parameters

Dominant systematic uncertainties on predicted rates

Quenching factor	25%
$\nu$ flux	10%
Nuc. form factor	5%
Analysis acceptance	5%

# CE $\nu$ NS observation data release

---

- Data that constituted CE $\nu$ NS observation has been packaged and is publicly available
  - <http://dx.doi.org/10.5281/zenodo.1228631>
  - <https://coherent.ornl.gov>
- Should include all information necessary to perform further analyses on CsI[Na] data
  - Binned data for coincidence and anticoincidence regions for both SNS on and off; prompt-neutron model
  - Descriptions and values for relevant systematics
- Collaboration intends to continue practice of data releases

# COHERENT physics moving forward

- Measure NINs cross section in  $^{208}\text{Pb}$ ,  $^{56}\text{Fe}$ 
  - Upgrades to detection system planned in cooperation with PROSPECT
- Measure  $^{127}\text{I}$  CC cross section
  - 185-kg NaI $\nu$ E collecting low-gain CC data now
  - Sensitivity to  $g_A$  quenching with  $Q \sim \mathcal{O}(10 \text{ MeV})$
- $N^2$  dependence of CE $\nu$ NS cross section
  - Several distinct  $N$  values represented in COHERENT suite of experiments
  - 22-kg LAr detector already collecting CE $\nu$ NS data, plans for 10 kg of Ge PPCs and multi-ton NaI[Tl]
- Begin to perform precision CE $\nu$ NS measurements
  - High-resolution, low-threshold detectors, such as Ge PPCs, enable access to exciting physics, e.g. electromagnetic properties of neutrinos

CENNS-10 LAr detector

NaI $\nu$ E: NaI[Tl] neutrino experiment

# Reducing dominant systematic uncertainties

## Quenching factors

- Understanding of QF is crucial for *all* CE $\nu$ NS measurements
  - Reanalyzing original data and collecting new data to resolve discrepancy in COHERENT QF measurements for CsI[Na]
  - Some data already collected and future measurements planned for Ge and NaI[Tl]

- Indirect approaches to flux determination possible (e.g., improved input for models or direct measurement of pion production at SNS)
- Conceptual design stages of a D<sub>2</sub>O detector for neutrino alley relying on CC interaction on D
  - D cross section is relatively well understood theoretically [1] and previous measurements agree with predictions [2]

$\nu$  flux  
normalization

# Future of COHERENT

- Next stages of COHERENT CE $\nu$ NS measurements will be a considerable scale up
  - Beginning plans for  $\mathcal{O}(1 \text{ ton})$  LAr detector using underground argon
  - Development advancing for multi-ton NaI[Tl] detector capable of simultaneous CC and CE $\nu$ NS measurement; designing new PMT-base electronics to facilitate this parallel measurement
- Flux normalization measurements benefit all COHERENT experiments; early design stages

# Only the beginning...

- CE $\nu$ NS predicted in 1974 but unobserved until 2017
  - Observed at 6.7- $\sigma$  level using 14.6-kg CsI[Na] scintillator deployed at pulsed, stopped-pion  $\nu$  source (SNS)
- COHERENT continues to search for CE $\nu$ NS with numerous detectors (LAr, NaI[Tl], Ge PPCs) in addition to several other efforts
  - Working towards performing *precision* CE $\nu$ NS measurements
- Many other groups seeking observation with many different kinds of detectors, different neutrino sources
  - Examples: CONNIE, CONUS, MINER, Nu-CLEUS, nuGEN, RICOCHET, RED-100
  - These efforts are *complementary*! Joint analyses using different detectors and/or sources are very powerful [1]
- Tremendous amount of physics left to be done with CE $\nu$ NS
  - Important complement to oscillation measurement program through lifting of LMA-D ambiguity

COHERENT SNS

Backup

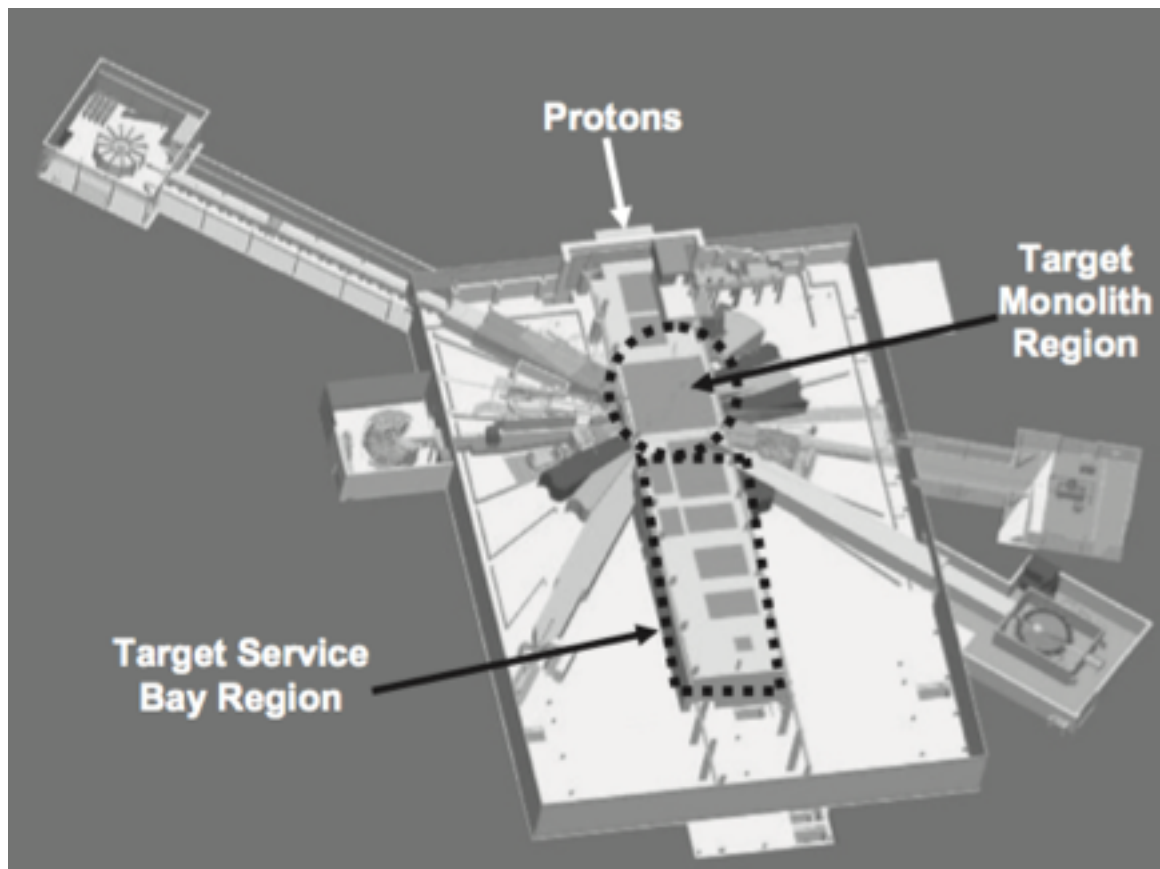

# Enter: The COHERENT Collaboration

- Goal: **unambiguous observation** of  $\text{CE}\nu\text{NS}$  using multiple nuclear targets / detector technologies
  - Leverage detector advances from dark-matter community
  - Utilize intense, pulsed neutrino source provided by Spallation Neutron Source (SNS)
  - Use of different nuclear targets allows for measurement of characteristic  $N^2$  cross-section dependence and some added analysis advantages
- Pioneering  $\text{CE}\nu\text{NS}$  detector:  $\text{CsI}[\text{Na}]$

# The Spallation Neutron Source

*Most intense pulsed neutron source in the world*

# Neutrons at the SNS

---

- Extensive neutron-background measurement campaign at various locations using several detector systems
- Leverages expertise and hardware from the various member institutions

# Neutrons at the SNS

## Coded-aperture neutron imager

- Built by ORNL collaborators
- Intended for nuclear security applications
- Takes a picture of target area “in neutrons”

Reminder: SNS is a billion-plus dollar facility dedicated to neutrons

Target is “visible” through monolith shielding on the instrument floor

# Low-energy nuclear recoils from CE $\nu$ NS

- Signature of CE $\nu$ NS in a detector is a low-energy nuclear recoil
- To properly interpret collected data, it is of paramount importance that detector response at these *nuclear recoil* energies be well understood
- Uncertainty in detector threshold translates into uncertainty in measured cross section
  - Situation worse for heavier targets

Figure from the COHERENT Collaboration

# Low-energy nuclear recoils from neutron scattering

- Quasi-monoenergetic neutron beam scattered by central detector into fixed angles covered by “backing” detectors; nuclear recoil energy kinematically well defined

$$\Delta E = 2E_n \frac{M_n^2}{(M_n + M_T)^2} \left( \frac{M_T}{M_n} + \sin^2 \theta - (\cos \theta) \sqrt{\left( \frac{M_T}{M_n} \right)^2 - \sin^2 \theta} \right)$$

# Tandem accelerator lab at TUNL

- 3 ion sources
- Beam can be bunched and chopped
- 10-MV maximum terminal voltage
- Numerous beam lines and experimental areas

# Quenching factor measurements at TUNL

- Elastically scatter quasi-monoenergetic neutrons into "backing detectors" at known angles
  - Each backing detector associated with events having well-defined nuclear recoil energies
- Determine QF from global values in range from 5 to 30 keVnr:  $8.78 \pm 1.66\%$

# Quenching factor measurements at TUNL

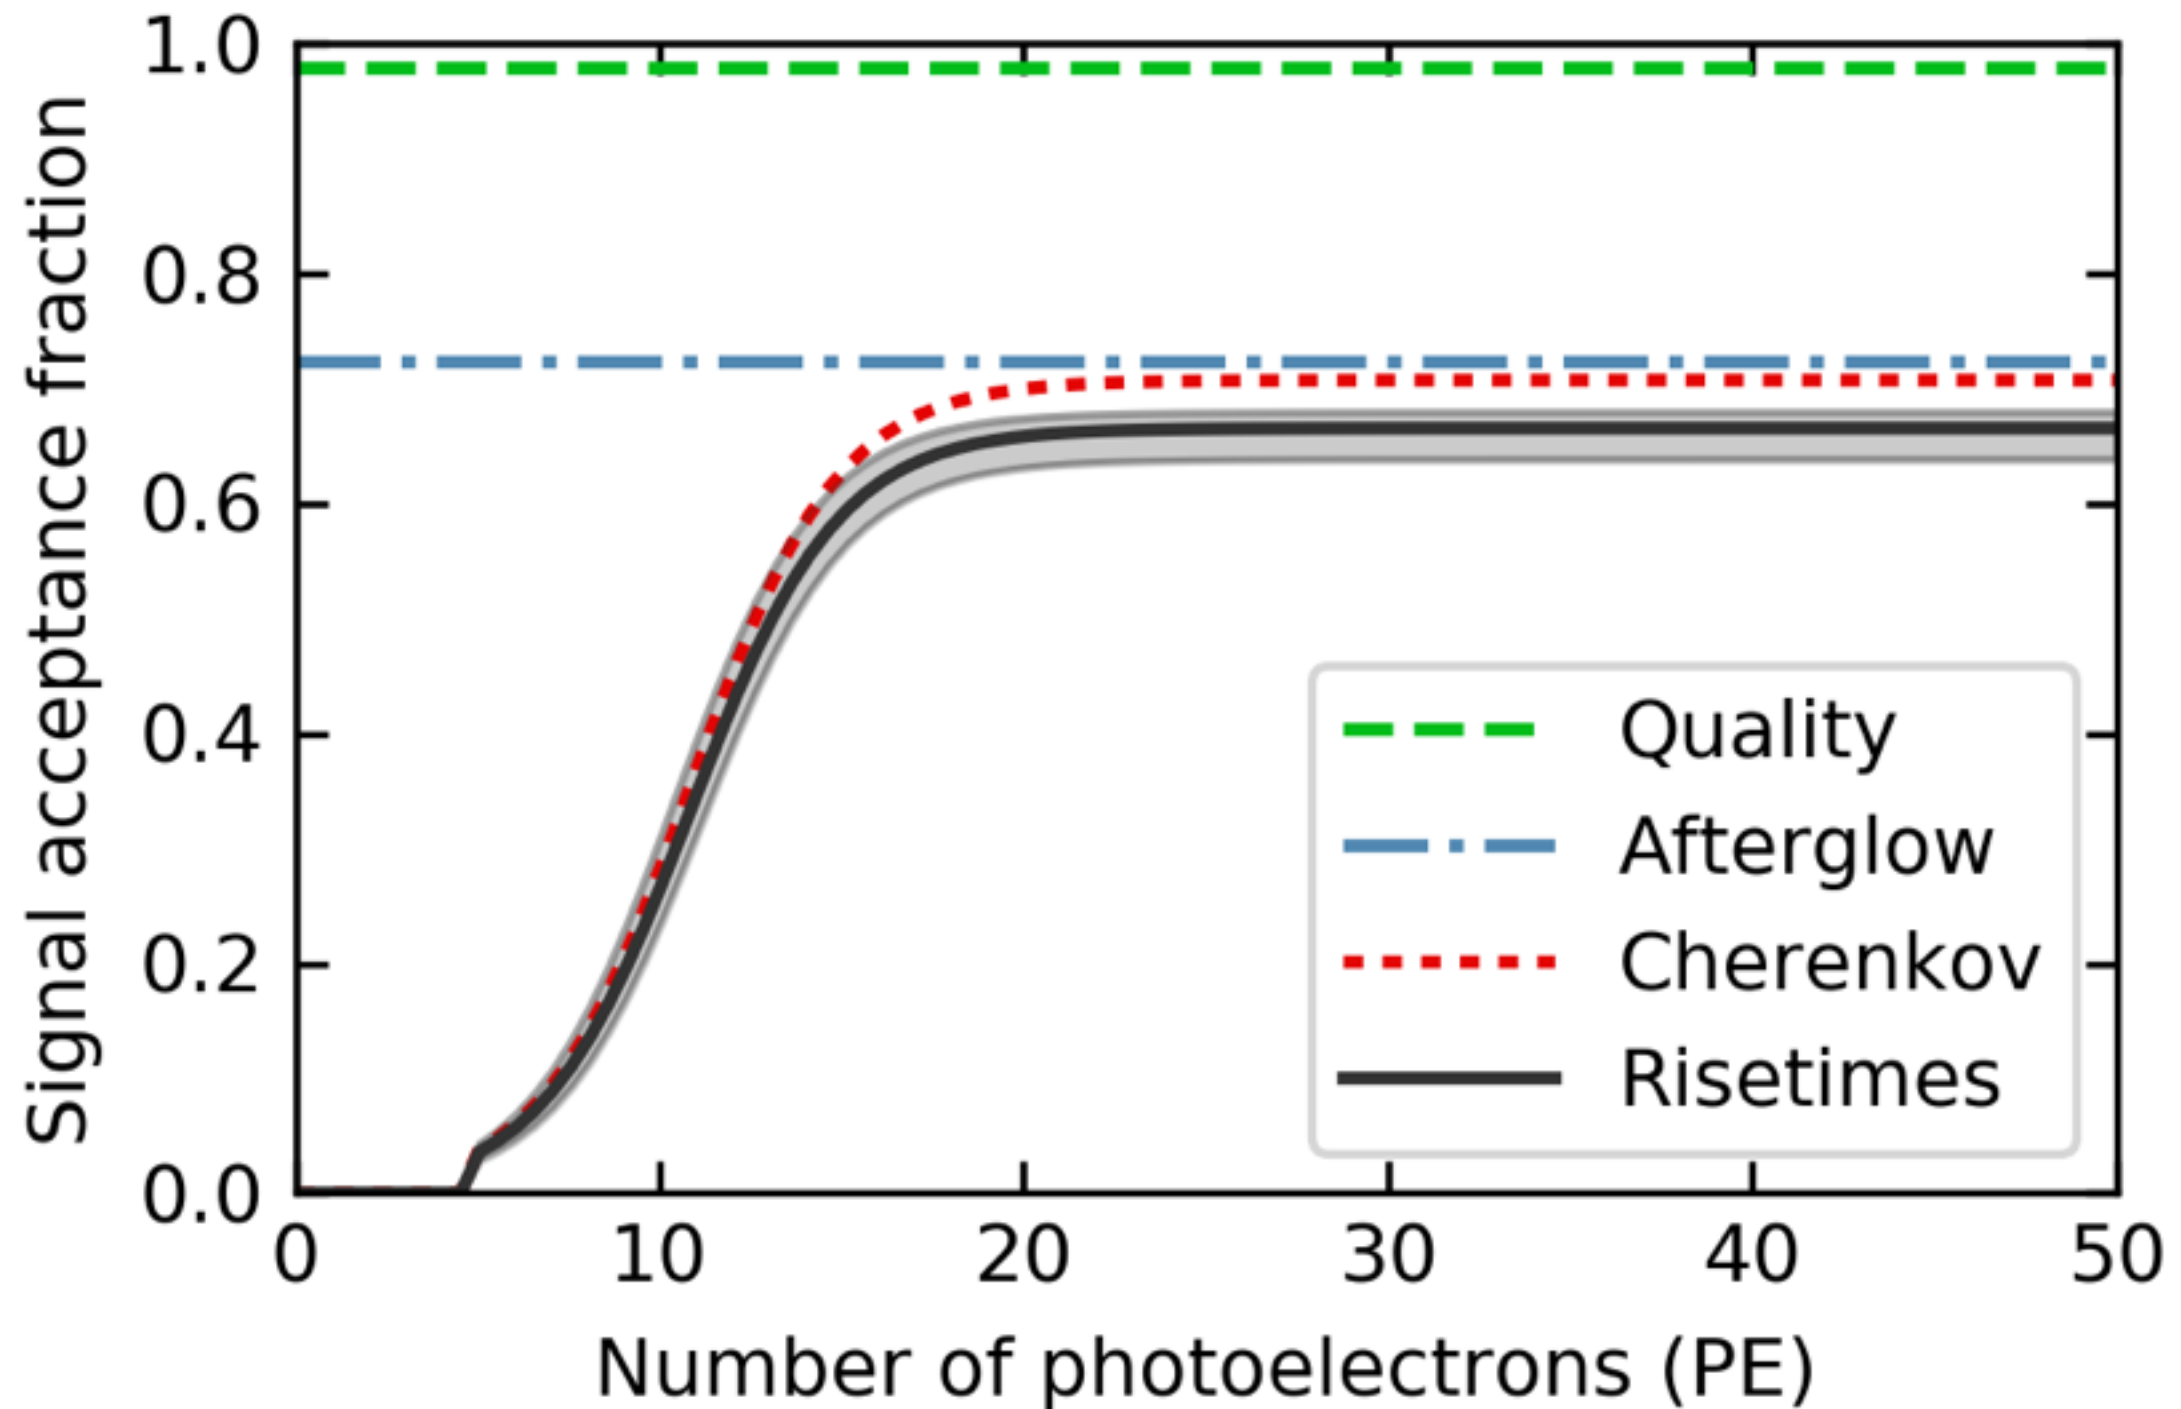

# CE $\nu$ NS with CsI[Na]

- Prior to deployment, careful characterizations in Chicago
- Uniformity along length confirmed
- Response to low-energy gamma rays assessed via small-angle Compton scattering
- Allows tuning of cuts to reject spurious events but accept low-energy depositions in the CsI

# Analysis acceptance efficiency

# CE $\nu$ NS with CsI[Na]

- Several layers of shielding
  - 7.5-cm-thick inner HDPE layer (addressing NINs)
  - 5-cm low-activity lead
  - 10-cm contemporary lead
  - 5-cm plastic-scintillator muon veto
  - 9+ cm water shielding on sides and top

# Rate and shape estimates

Raw CEvNS recoils

Observed CEvNS recoils

- Predict recoil distributions assuming SM - convert to photoelectrons using carefully determined calibrations
- *In situ* neutron measurements inform spectral model of prompt SNS neutrons
- Acceptance efficiency applied to models to produce beam-power-normalized PDFs in energy space

# Background model for 2-D

- Background model informed by anti-coincidence dataset
- Use “factorized” approach taking advantage of uncorrelated energy/time features
- Exponential fit to time projection, then used with energy projection to define model

# Stability and general health checks
