

# Class starts after this song... and some more

*King Gnu – Specialz (2023)*

*requested by Jacob Lee (TA-of-CM7)*

I am a sophomore double majored in CompSci and Mechanical Engineering. I am interested in robotics. In my free time, I enjoy playing games (board games and video games). I am adopted from Korea. I have anaphylactic food allergies to nuts, seeds, and lentils.

# Bipartite Matching

- **Matching**, but with the underlying graph already bipartite:  
$$G = (L \cup R, E)$$
  - **Matching** TAs/residents/interns with positions
  - **Matching** computing tasks with machine cycles/slots
  - ... but **NOT**: ~~matching men with women~~
  - These applications often involves preferences and some additional ideas of what an *optimal* matching looks like (stable, fair, ...)
  - We will just discuss **whether a perfect matching exists**
-

# Hall's theorem (for the special case $|L| = |R|$ )

- Theorem.

A bipartite graph  $G = (L \cup R, E)$  has a perfect matching if and only if

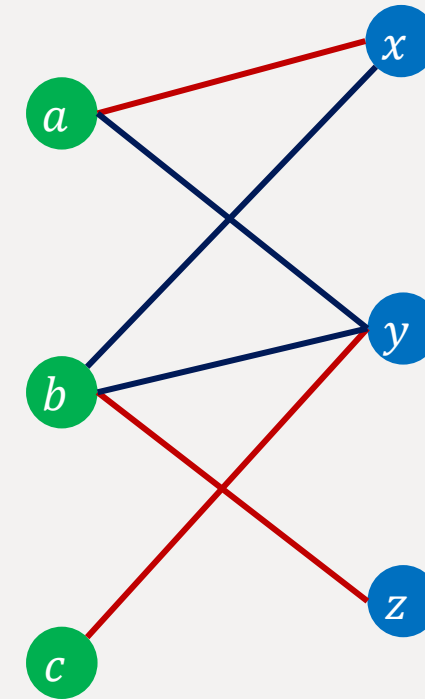

Hall's condition

for any subset  $S \subseteq L$ , the size of the image of  $S$  w.r.t.  $E$ ,  $N(S)$ , is at least as large as  $|S|$ .

- $N(S)$  is just the set of all vertices in  $R$  that are connected to some vertices in  $L$  by edges in  $E$

# Terminology Practice

$S$	$ S $	$N(S)$	$ N(S) $	Hall's condition satisfied?
$\{a\}$	1	$\{x, y\}$	2	Yes
$\{b\}$	1	$\{x, y, z\}$	3	Yes
$\{c\}$	1	$\{y\}$	1	Yes
$\{a, b\}$	2	$\{x, y, z\}$	3	Yes
$\{a, c\}$	2	$\{x, y\}$	2	Yes
$\{b, c\}$	2	$\{x, y, z\}$	3	Yes
$\{a, b, c\}$	3	$\{x, y, z\}$	3	Yes

# Proof of Hall's theorem (1)

- Part 1. perfect matching exists  $\Rightarrow$  Hall's condition
    - Simple prove by contradiction: assume Hall's condition doesn't hold
    - Then there exists a subset  $S \subseteq L$  such that  $|N(S)| < |S|$
    - But if a perfect matching exists, every vertex in  $S$  needs to match with a distinct vertex in  $N(S)$ , which means  $|N(S)| \geq |S|$ , a contradiction
-

# Proof of Hall's theorem (2)

- Part 2. Hall's condition  $\Rightarrow$  perfect matching exists
  - The set of **balanced** bipartite graphs,  $\mathcal{B}$ , can be alternatively defined as:
    - **Base Case:**  $G = (\emptyset \cup \emptyset, \emptyset) \in \mathcal{B}$  (the “empty graph”)
    - **Constructor Case:** If  $G = (L \cup R, E) \in \mathcal{B}$ , then:
      - $G = ((L \cup \{l\}) \cup (R \cup \{r\}), E \cup E') \in \mathcal{B}$   
 (“adding one vertex to each side, then add some edges”)
      - ... this is hard to work with! We will instead resort to a (weak) induction
-

# Proof of Hall's theorem (2)

- Part 2. Hall's condition  $\Rightarrow$  perfect matching exists for all  $|L| = |R| = n$
  - **Proof:**
    - **Base Case.**  $n = 0$ . For  $G = (\emptyset \cup \emptyset, \emptyset)$ ,  $\emptyset$  is a perfect matching (yes it is)
    - **Inductive Hypothesis.** Assume the theorem holds for  $n = k$  for  $k \geq 0$ .
    - **Induction Step.** Consider a graph  $G = (L \cup R, E)$  with  $|L| = |R| = k + 1$ .
      - Case 1. Hall's condition is loosely satisfied (equation never holds).
      - Case 2. Hall's condition is tightly satisfied (equation holds for some  $S$ ).
-

# Proof of Hall's theorem (2-1)

- Part 2-1. Hall's condition loosely satisfied  $\Rightarrow$  perfect matching exists
  - **Induction Step.** Consider a graph  $G = (L \cup R, E)$  with  $|L| = |R| = k + 1$  such that for all  $S \subseteq L$  we have  $|N(S)| > |S|$ .
    - Pick an arbitrary left vertex  $l \in L$  and match  $l$  with an arbitrary right vertex  $r \in N(\{l\})$
    - Consider the remainder graph  $G' = (L - \{l\} \cup R - \{r\}, E')$  with  $k$  vertices each side.
    - Now for all  $S' \subseteq L - \{l\}$ , we have  $|N'(S')| \geq |N(S')| - 1 \geq |S'|$ .
    - In other words, Hall's condition is still satisfied (not necessarily loosely) for  $G'$ .
    - Any perfect matching of  $G'$  plus  $(l, r)$  is a perfect matching for  $G$ !
-

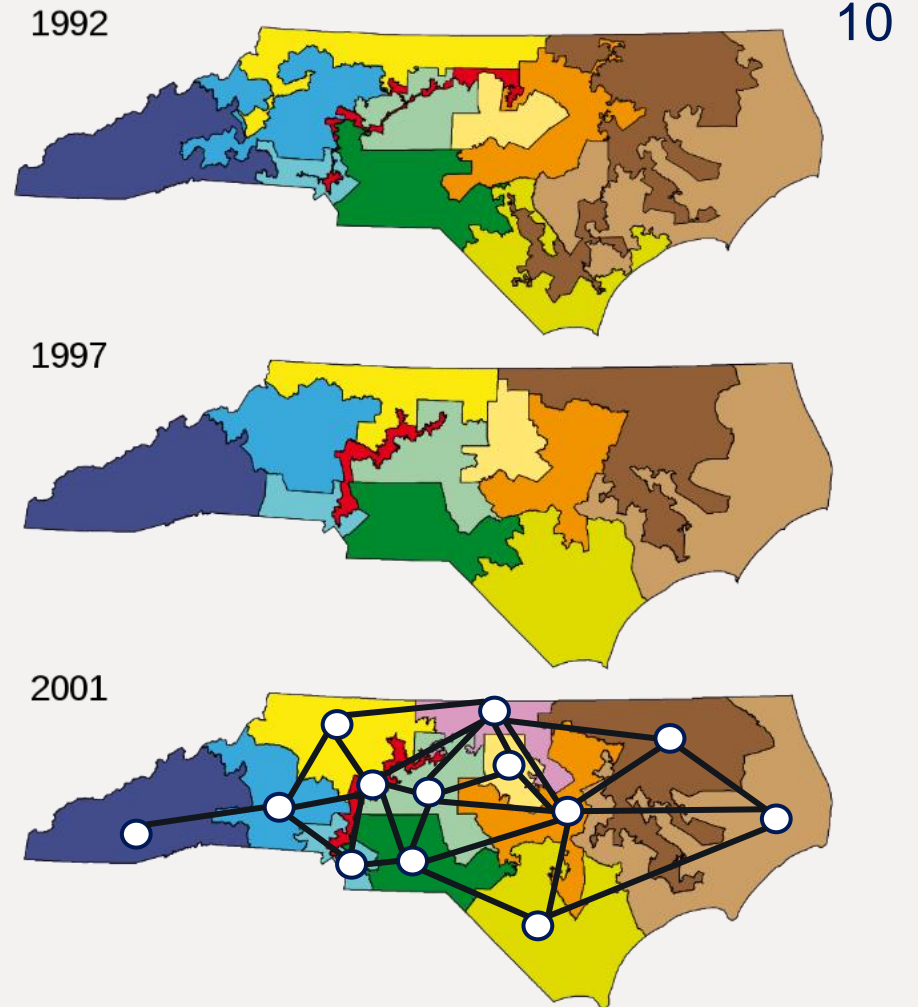

# Proof of Hall's theorem (2-2 - *skeleton*)

- Part 2-2. Hall's condition **strictly** satisfied  $\Rightarrow$  perfect matching exists
  - **Induction Step.** Consider a graph  $G = (L \cup R, E)$  with  $|L| = |R| = k + 1$  such that for all  $S \subseteq L$  we have  $|N(S)| \geq |S|$  and the equality holds for at least one  $S$ .
    - Find a perfect matching between  $|S|$  and  $|N(S)|$
    - Consider the rest of the graph without  $|S|$  and  $|N(S)|$ 
      - We can show Hall's condition still holds for this remainder graph
      - Therefore there is a perfect matching for this remainder graph; combine the two parts gives a perfect matching for the entire graph
-

# Coloring planar graphs

- Real-world maps are usually colored to delineate boundaries of regions
  - Here the regions are electoral districts of NC
- We can abstract away the geometry by considering each region as a vertex
- Add an edge between neighboring regions
- Map coloring becomes graph coloring

# Four-color theorem

- Theorem: **Every planar graph is 4-colorable**
  - Famous as the first math theorem that's first proved via the assistance of a computer (Appel & Haken, 1976)
  - The weaker theorem that states **every planar graph is 5-colorable** does not need the help from a computer, but is still too long (and requires many lemmas on planar graph properties) to fit into our class
  - See MCS Chapter 13 (entirely devoted to planar graphs) for a thorough read

Equivalence relations

Partial orders

No Answers Chosen

Possible answers

$uRv$  if there is a path between vertex  $u$  and vertex  $v$  in a simple undirected graph

$uRv$  if there is a path from vertex  $u$  to vertex  $v$  in a directed acyclic graph (DAG)

# Recursively Defined Structures, Revisited

- Example 3. The set of (undirected) binary trees,  $\mathcal{T}$ , can be defined as:

- **Base Case:**  $T = (\emptyset, \emptyset) \in \mathcal{T}$  (the “empty tree”)

- **Constructor Case:** If  $T_1, T_2 \in \mathcal{T}$ , then

# Partial Order of Recursively Defined Structures

# Topological Sort of Recursively Defined Structures

- How to obtain this order? We can use a modified DFS

# strong induction = structural induction

- Obtain a topological sort of the recursively defined structure
- Number elements (0), 1, 2, ... using this order
- Do strong induction on this order
  
- So anything achievable by structural induction is also achievable by strong induction

# All inductions are the same

- weak induction = strong induction (CM5)
- weak induction can be simulated by structural induction (last week)
- structural induction can be simulated by strong induction (we just saw it)
- Therefore, weak induction = strong induction = structural induction

all inductions are the same

If ~~weak induction = strong induction~~,

- why do we teach/learn them as separate?
  - Equally powerful, equally correct, **NOT necessarily equally comprehensible**
  - Certain inductions more readable in weak/strong/structural form
-
