COHERENT NEUTRINO NUCLEUS
INTERACTION EXPERIMENT

Juan Estrada for the CONNIE Collaboration

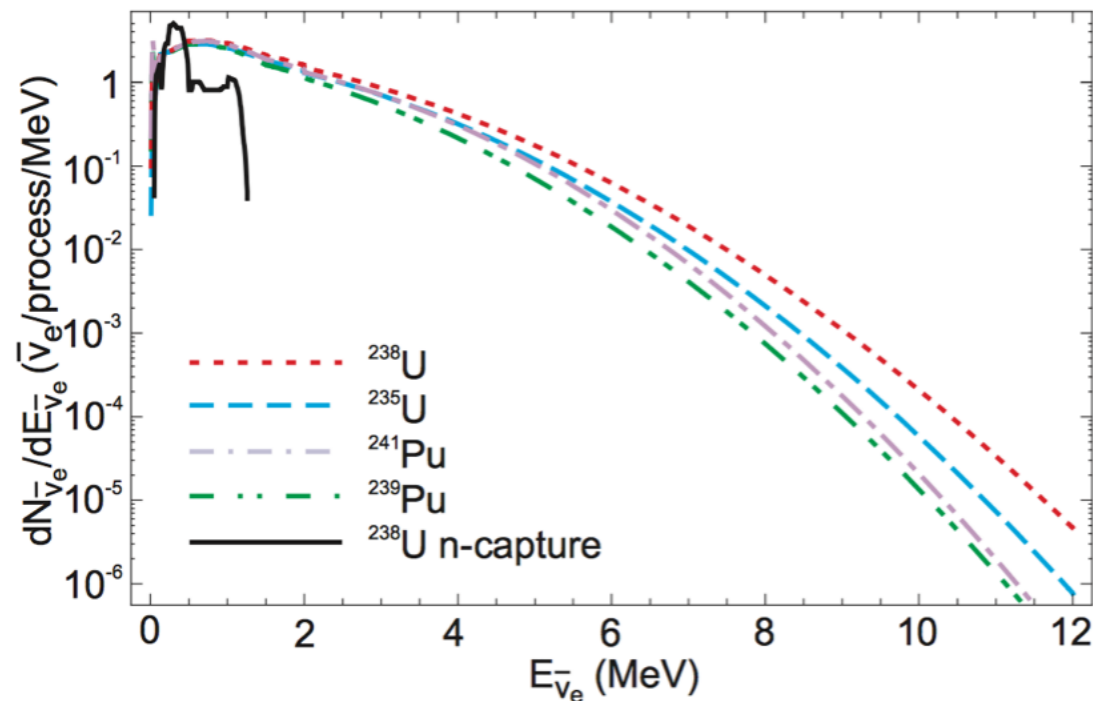

At low recoil energies ($T_A < 50$ MeV) the cross section is enhanced by $\sim N^2$.

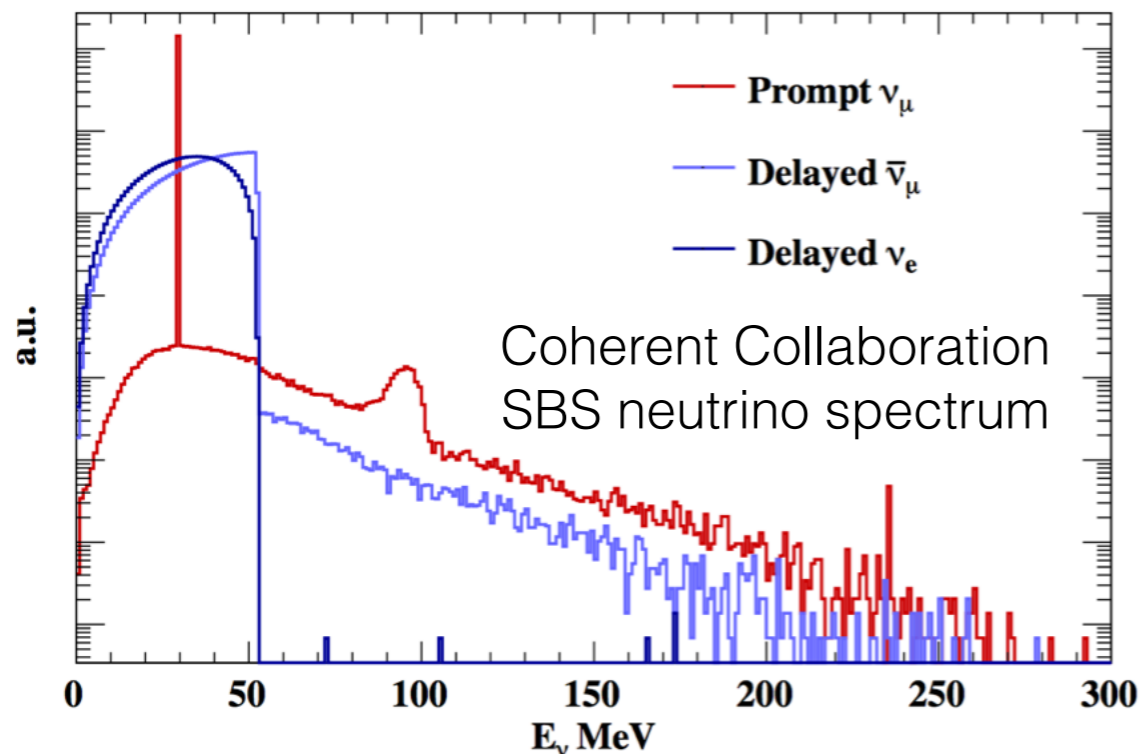

Coherent elastic neutrino-nucleus scattering (CEvNS) is a prediction of the Standard Model.

Two ways to get high flux low energy neutrinos

Neutrinos from a nuclear reactor

- Very large flux, close to core.
- Low energy recoils, harder to see.
- Deal with background by shielding.
- A window to very low energy neutrino sector.
- MINER, **CONNIE**

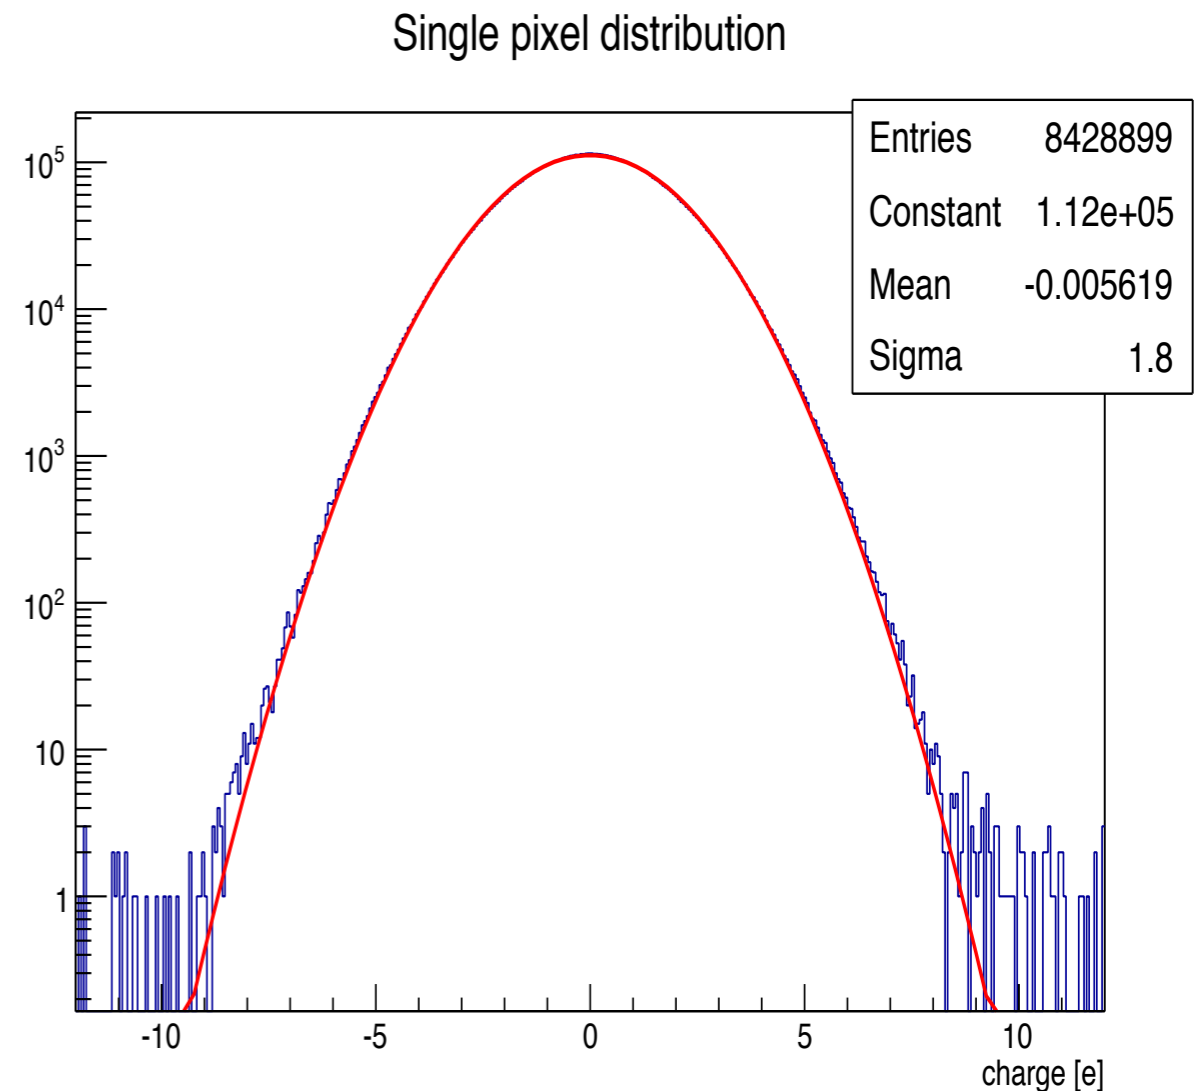

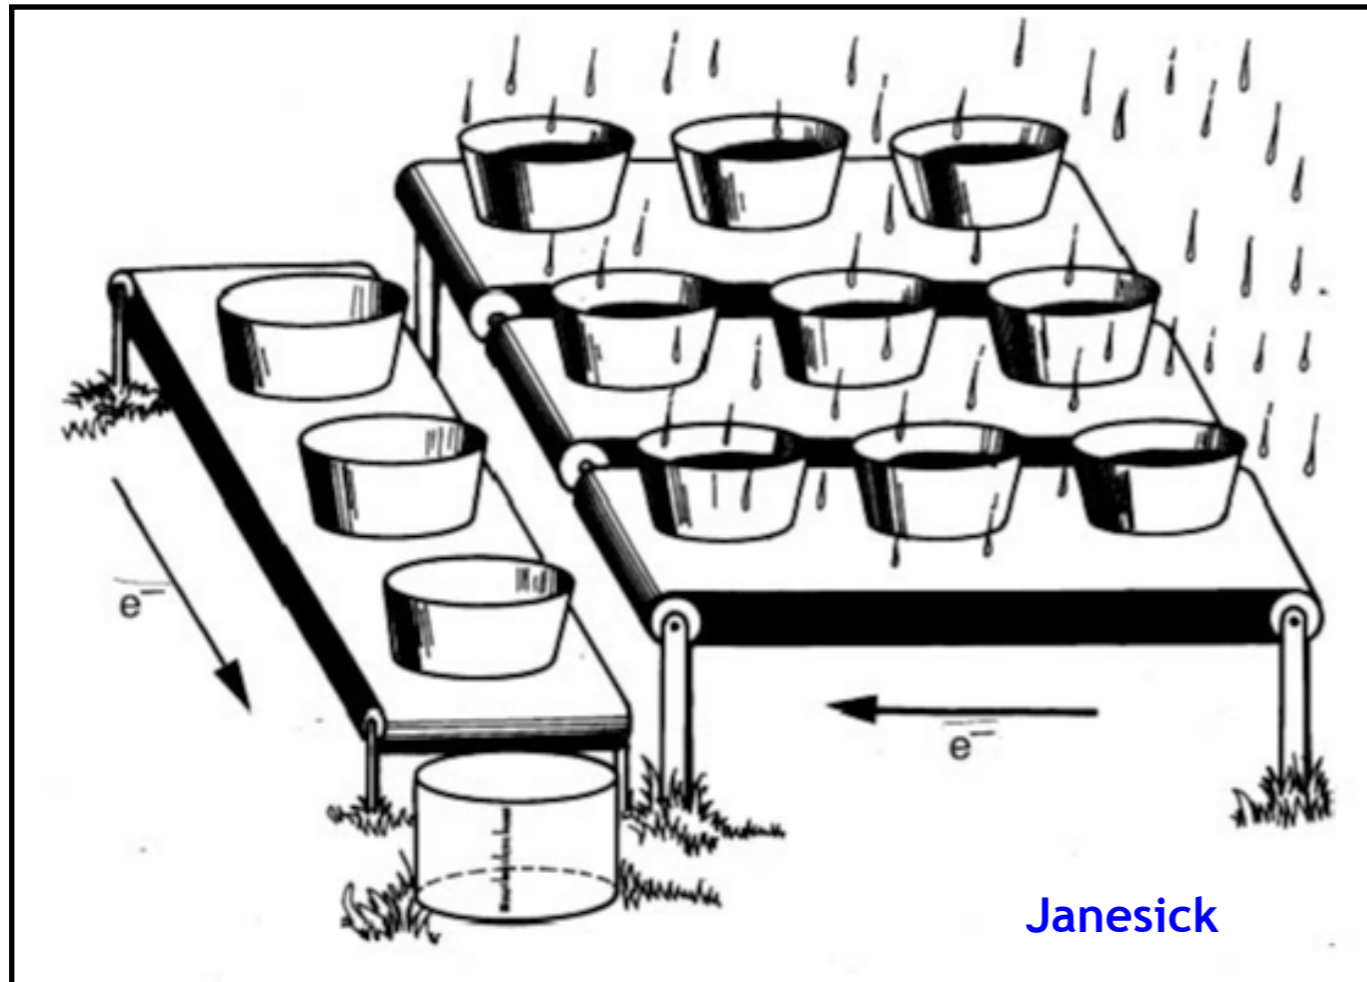

Neutrinos produced by stopped pions (decay at rest).

- Higher energy recoils, easier to see
- Pulsed to control background.
- Has to deal with beam associated background.
- COHERENT

Detector: CCD readout

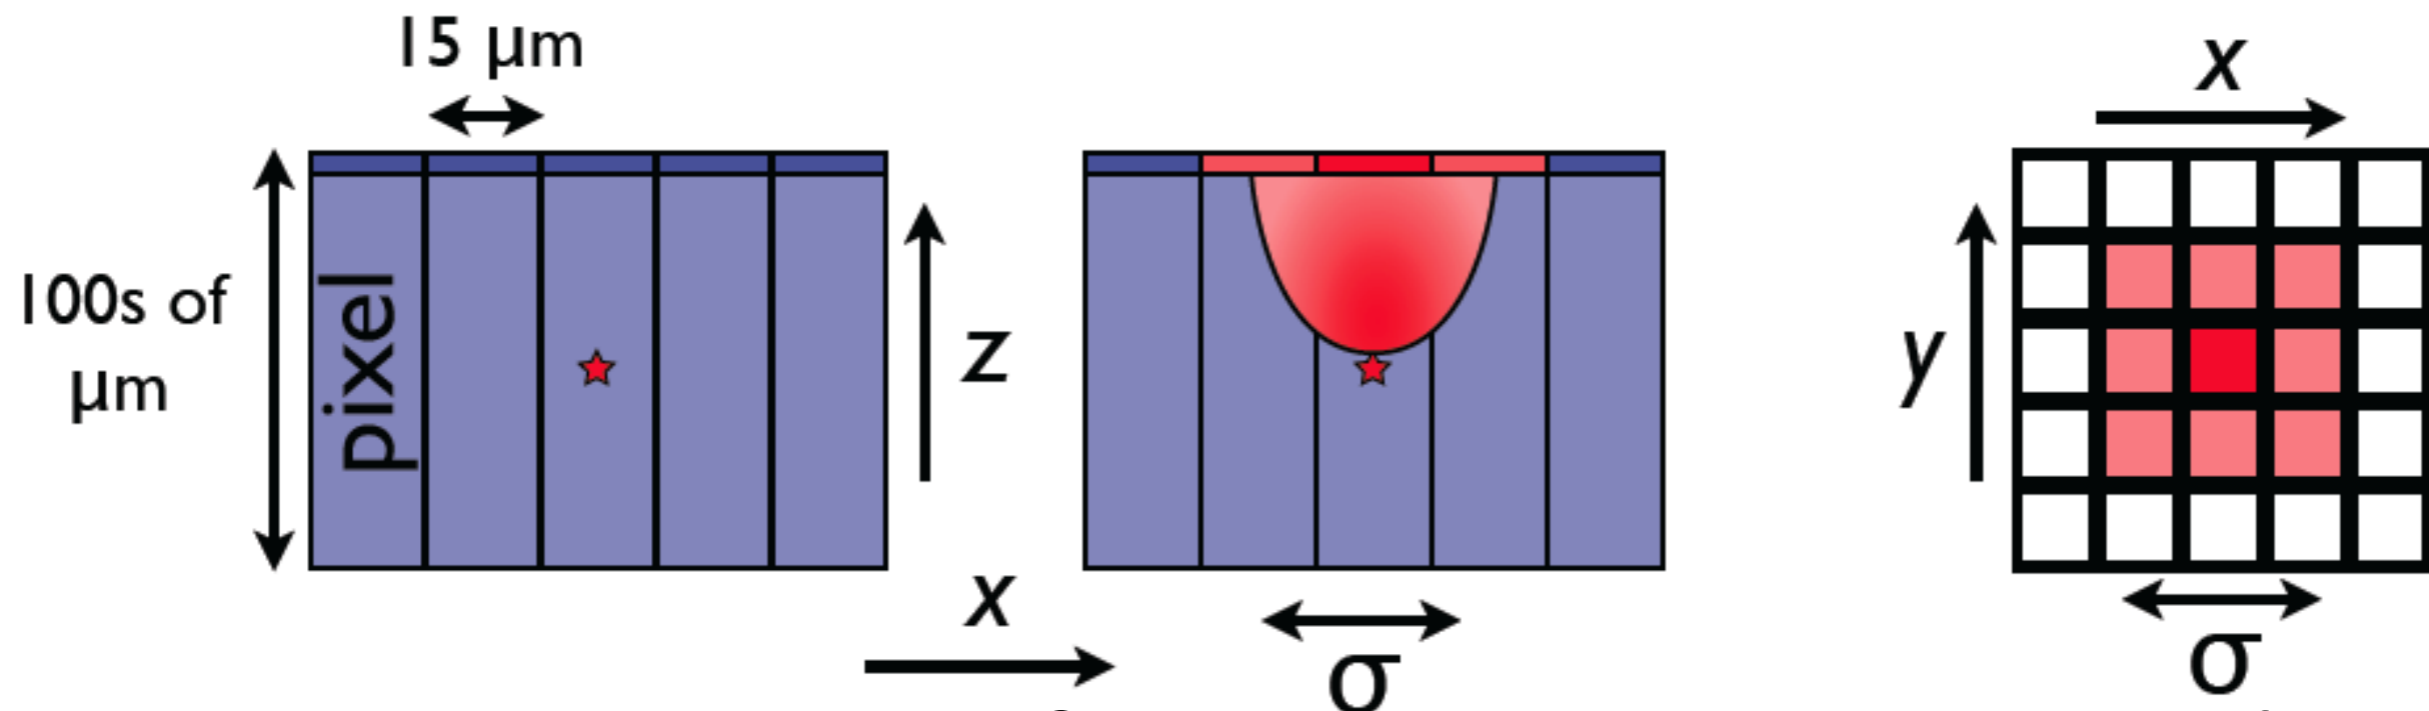

Charge coupling makes the detectors ideal for low noise measurements, typical noise for scientific CCDs is $2e^-$ RMS (7.6eV). Very recent work pushing this to “0” noise.

(a) A CCD pixel

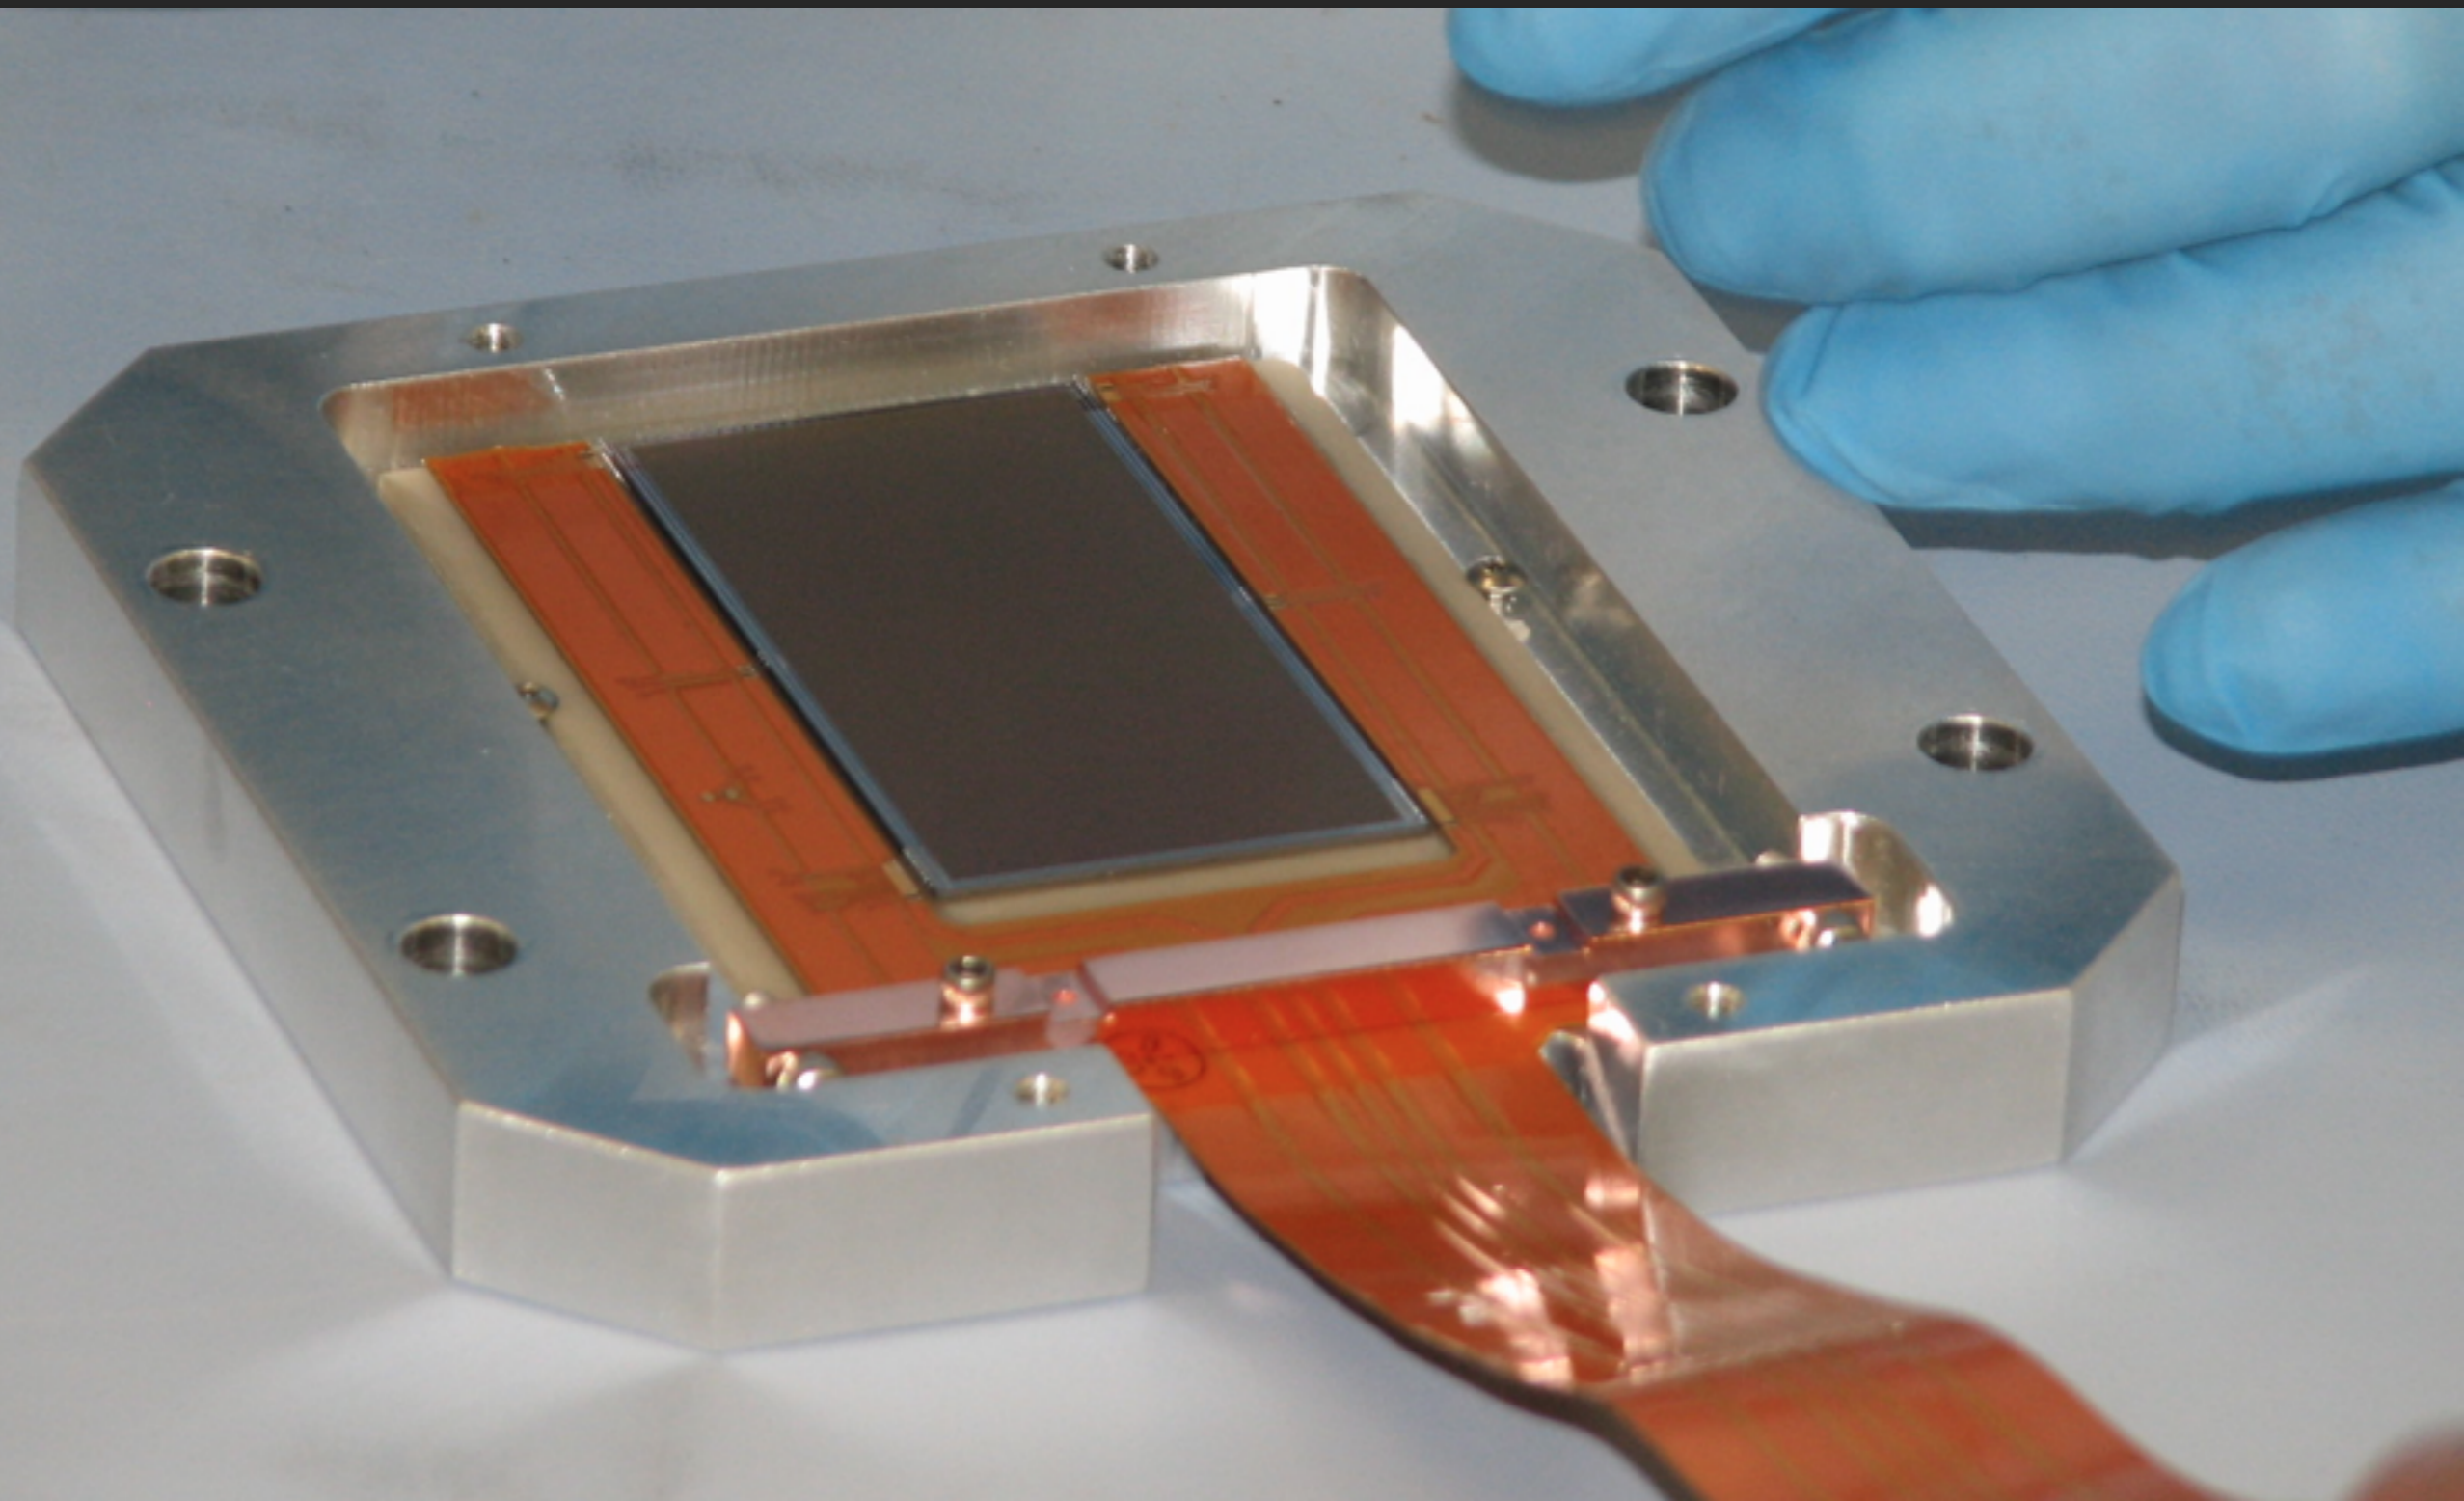

(b) WIMP detection principle

Recent developments by the MSL group at LBNL has allowed the fabrication for “massive” CCDs. 675 μm is now possible.

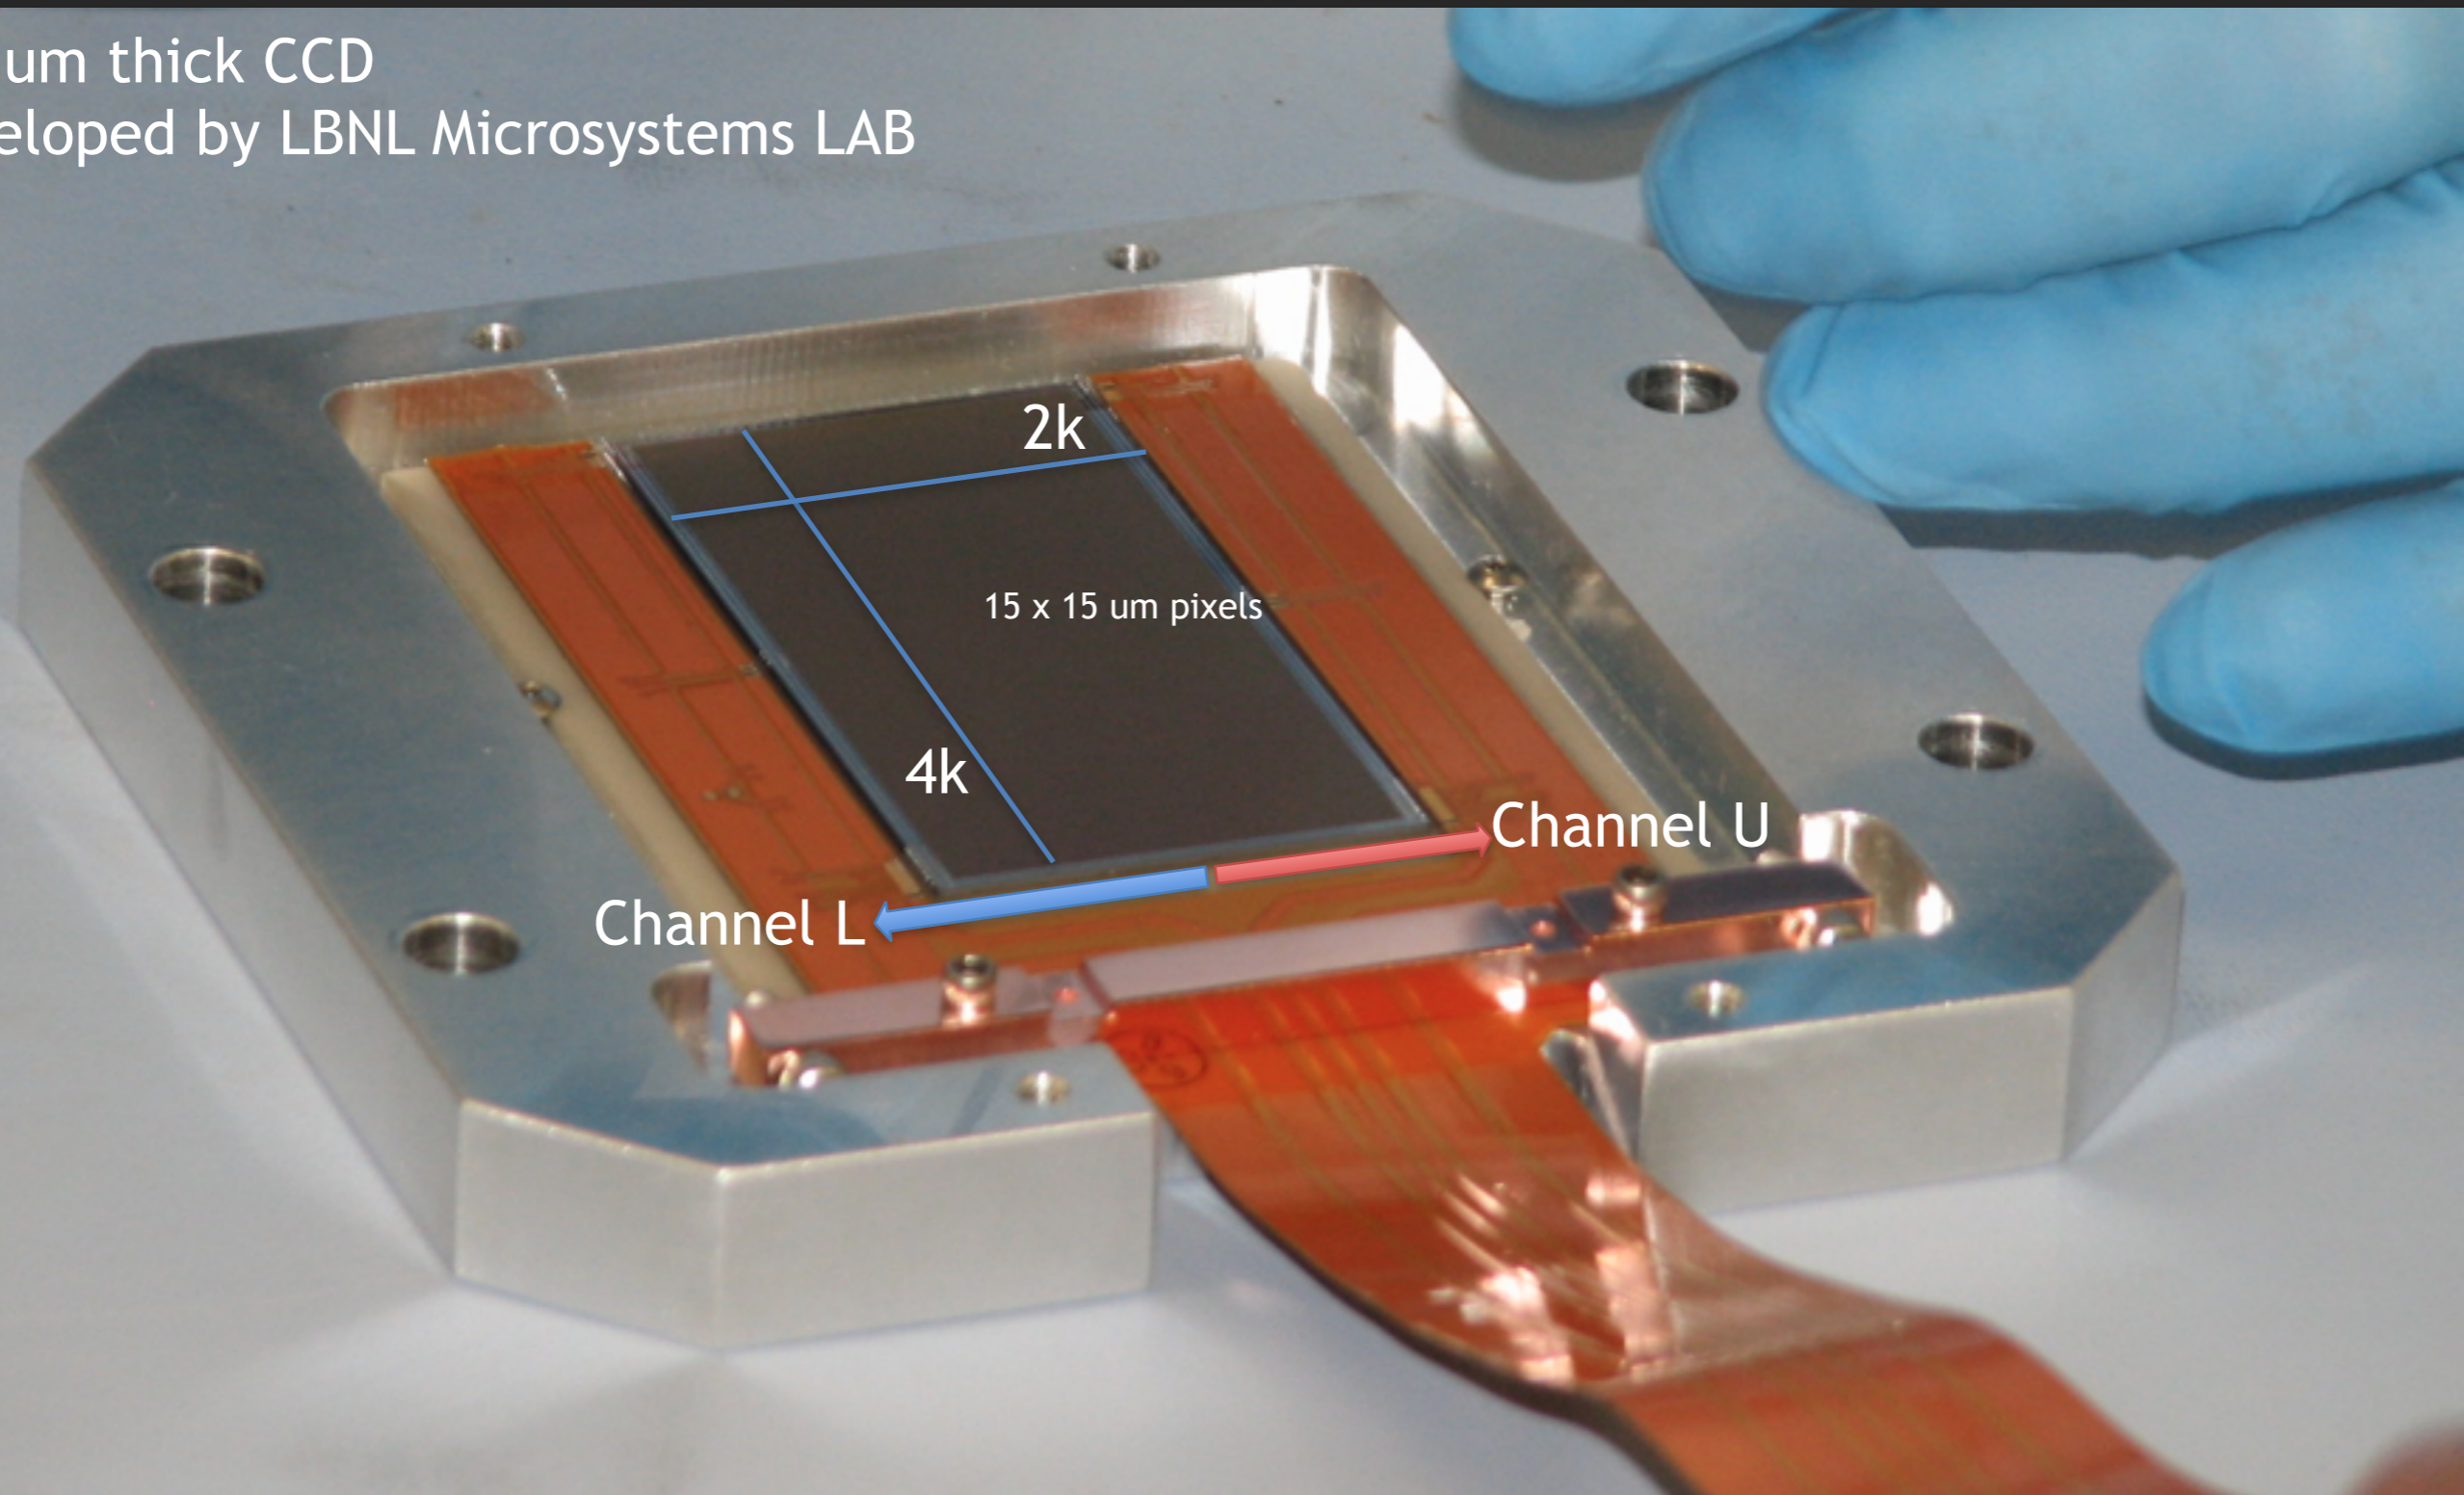

CONNIE 2014-2015 sensor:

CONNIE 2014-2015 sensor

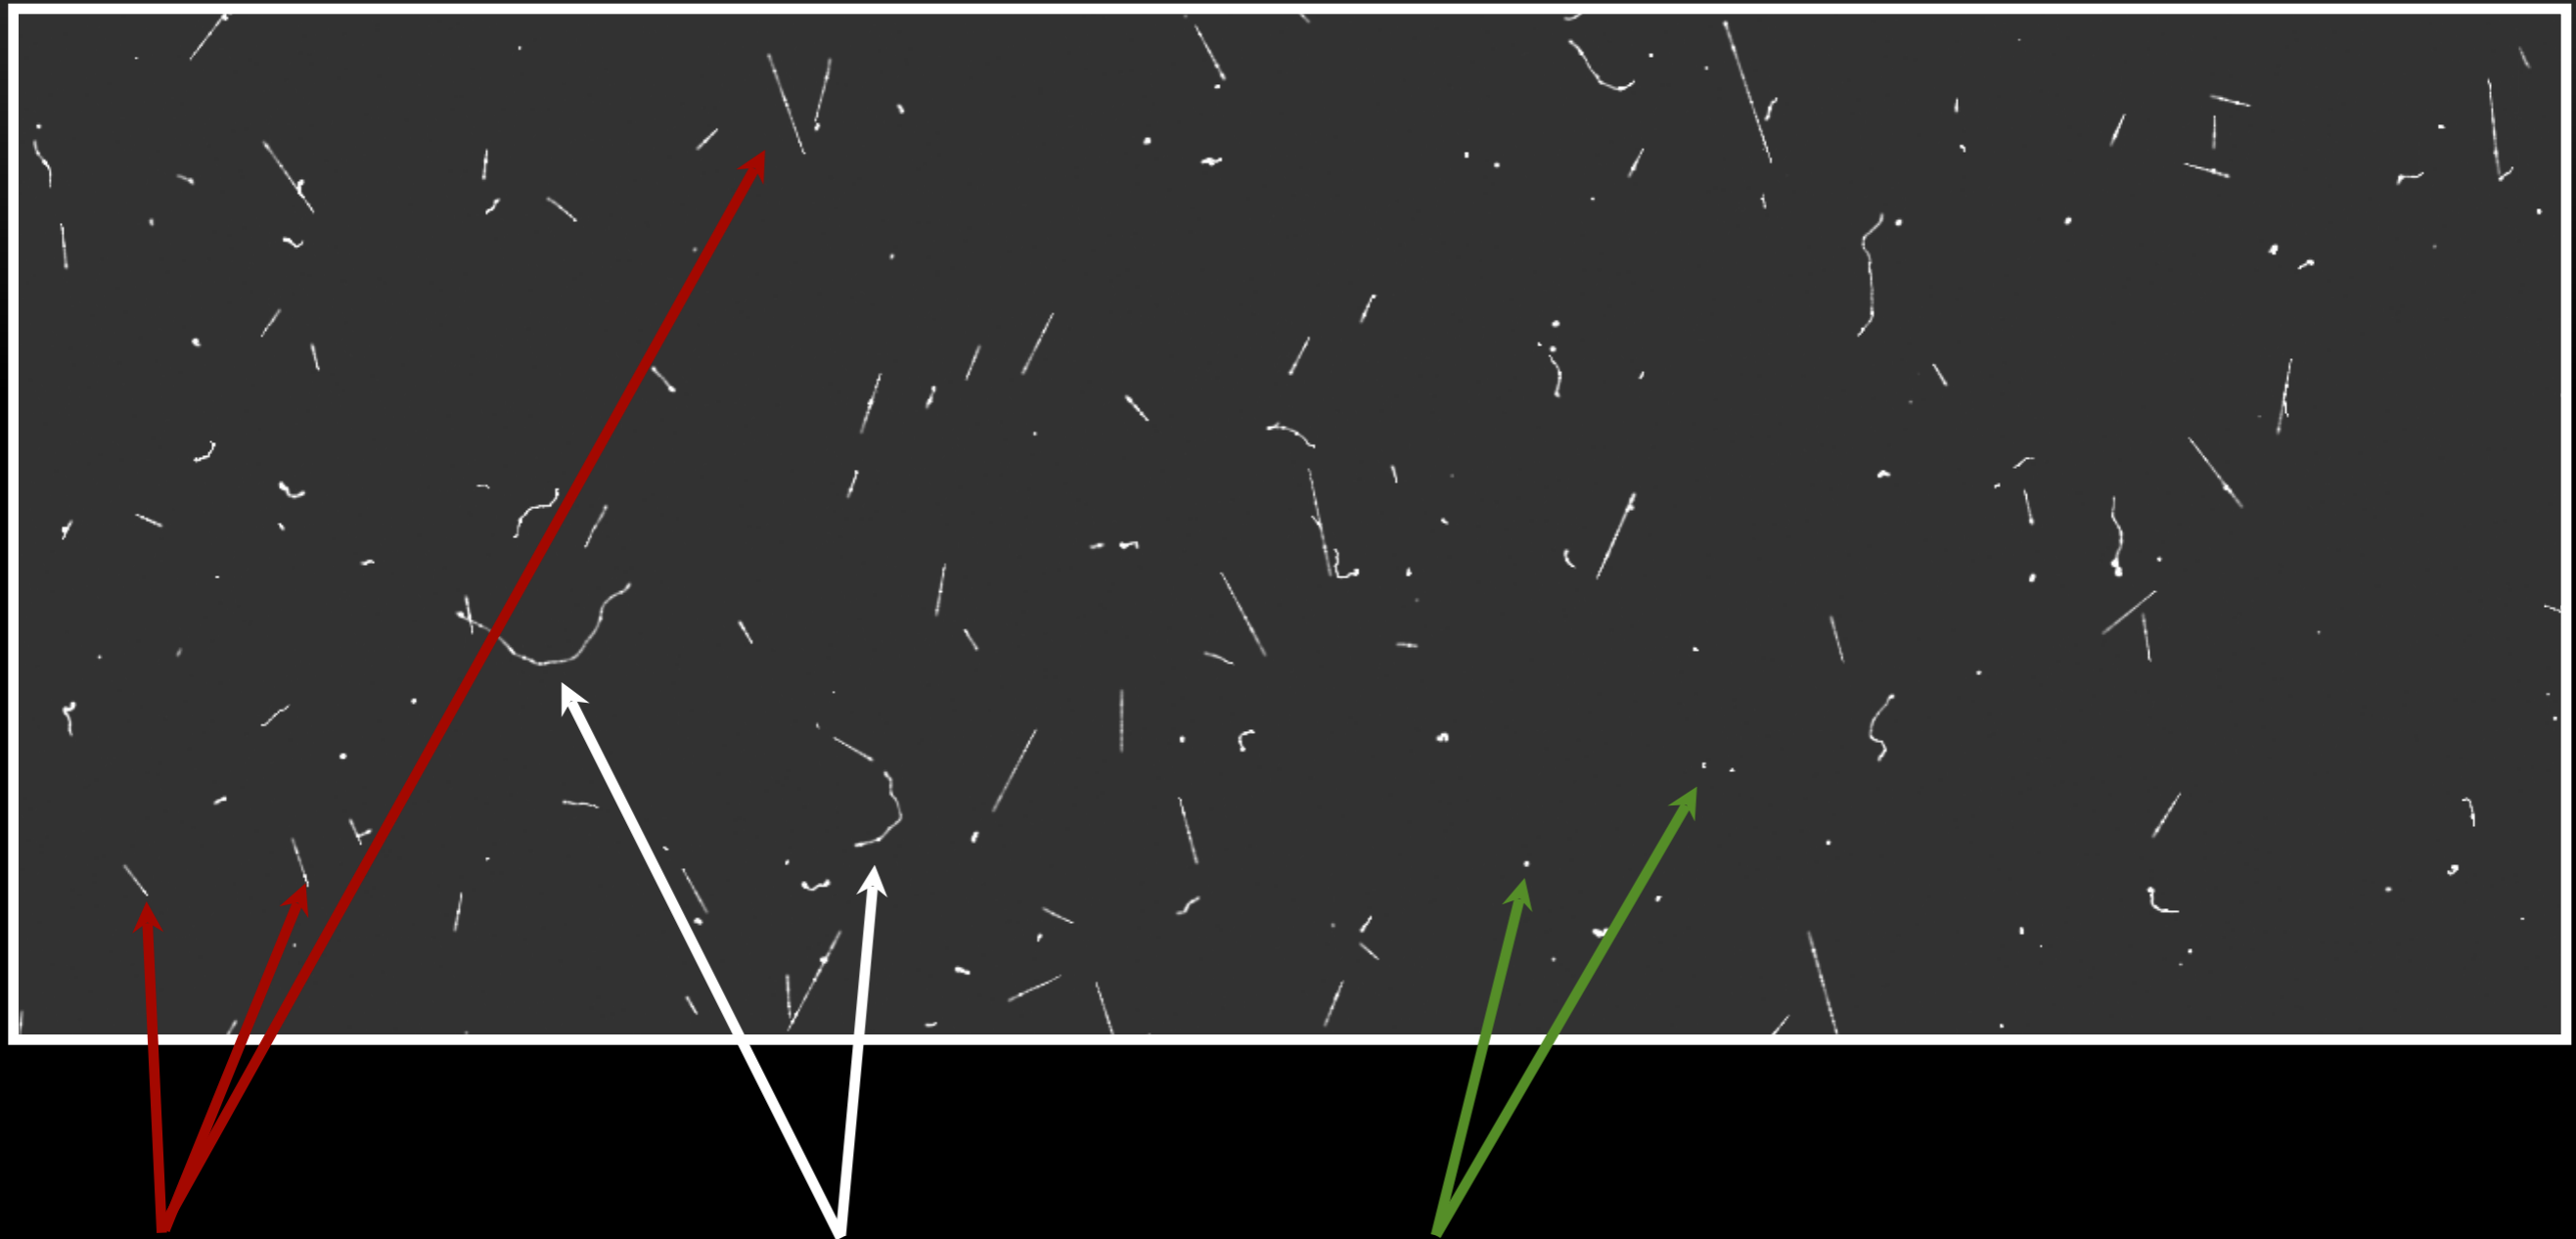

250 μm thick CCD

Developed by LBNL Microsystems LAB

The noise is determined by the capacitance of the output node.
The active pixels are decoupled from the readout node!

Particle identification in a CCD image

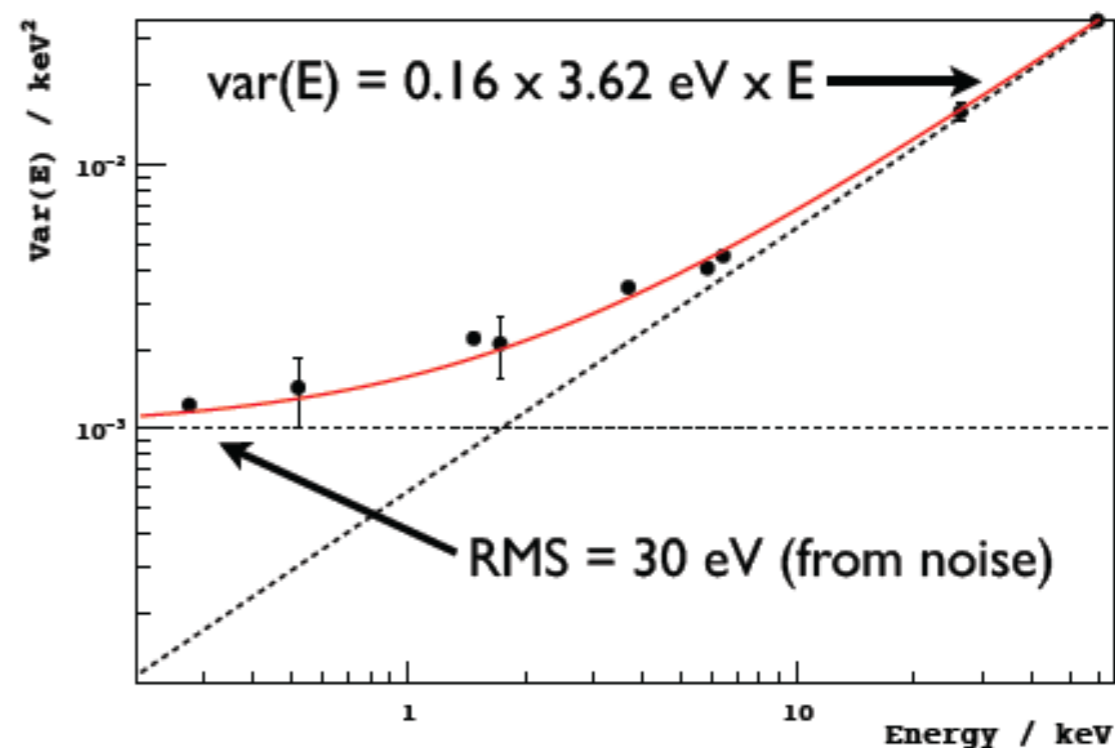

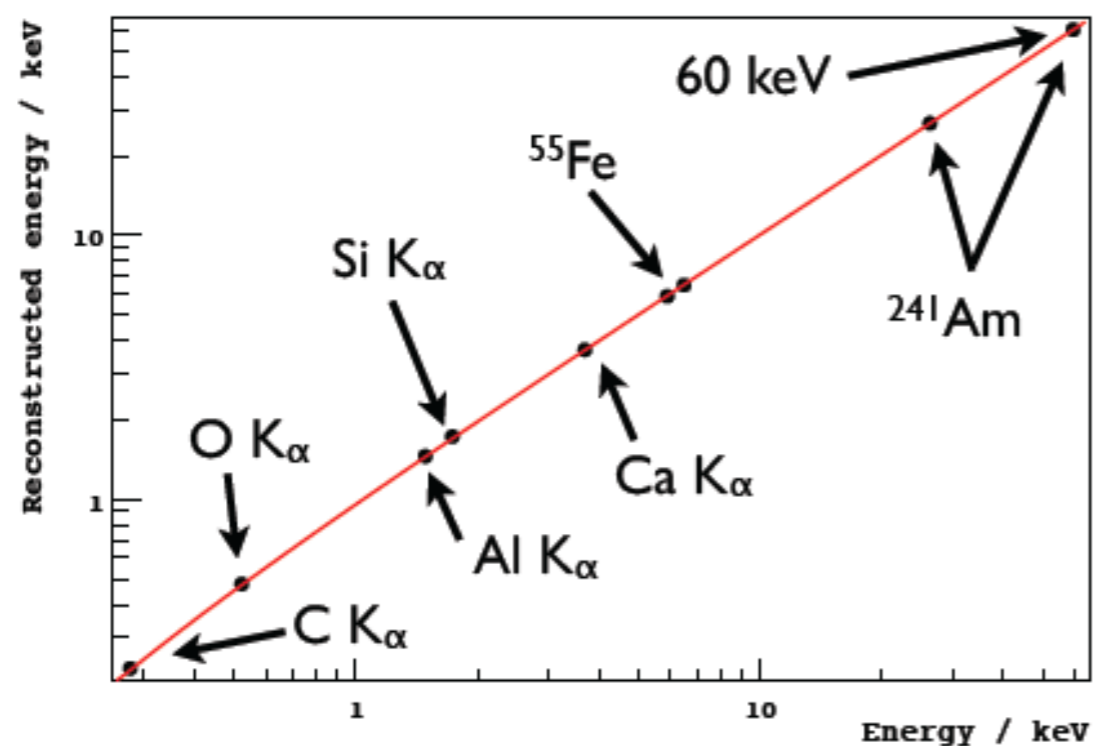

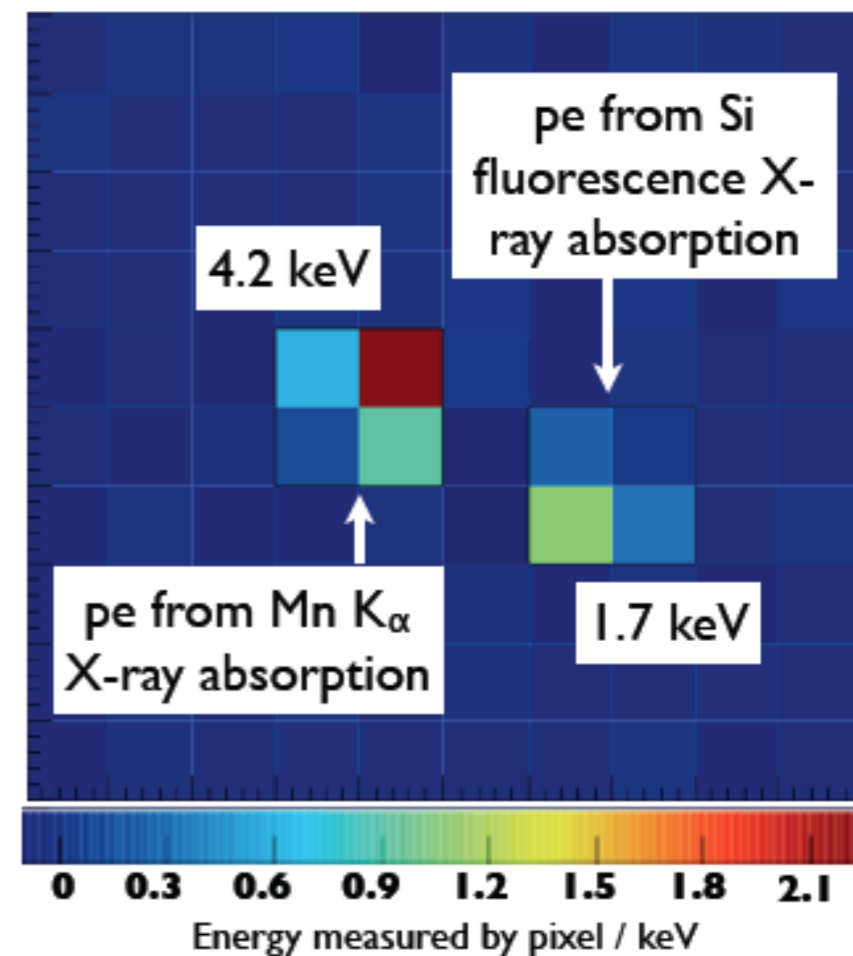

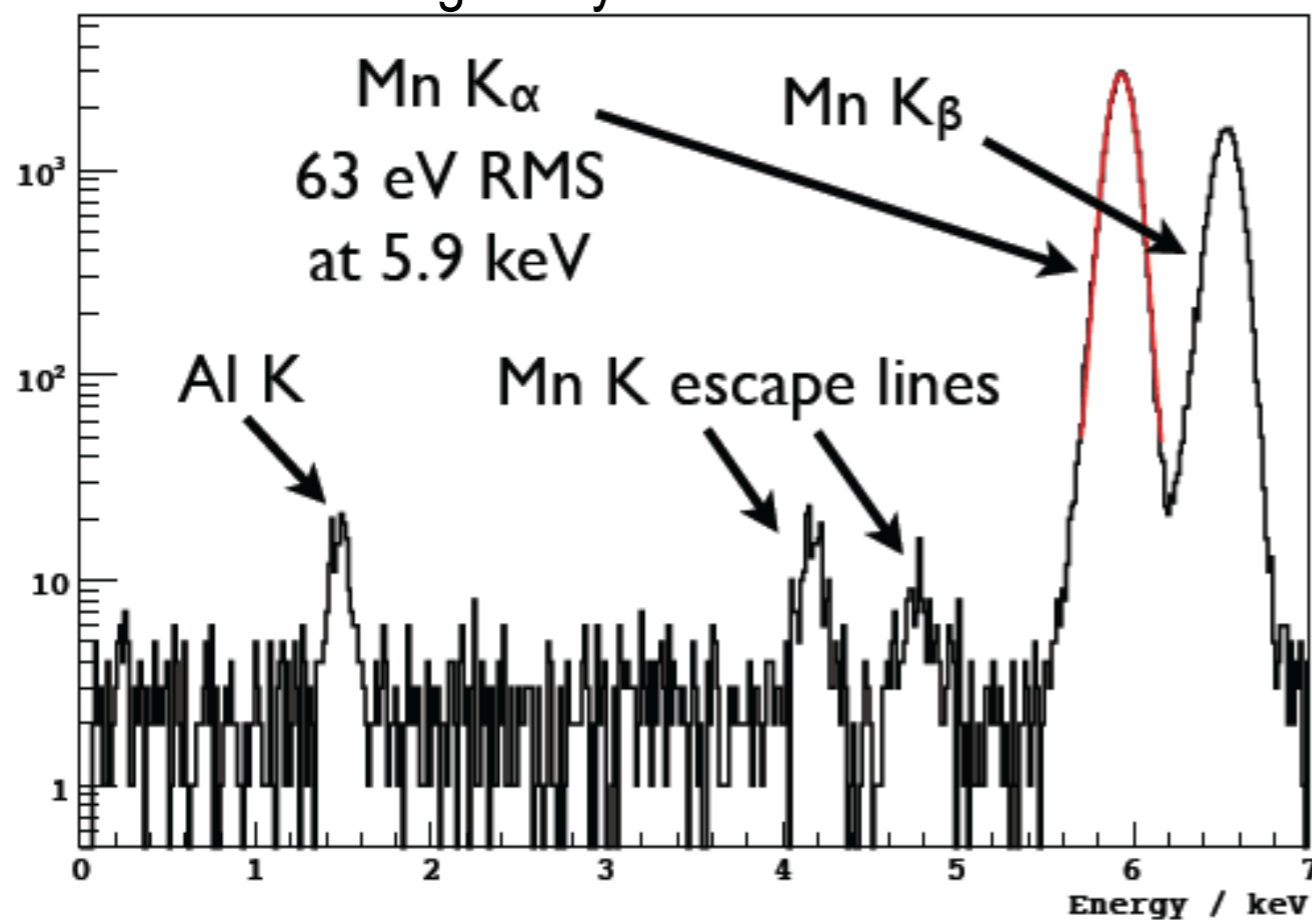

muons, electrons and diffusion limited hits.

Nuclear recoils will produce diffusion limited hits. Neutrinos from reactor are expected to produce nuclear recoils at a rate of 10,000 per day for each kilogram of detector.

Calibration using X-rays

Nuclear Recoil Calibration (A.Chavarria et al)

arXiv:1608.00957

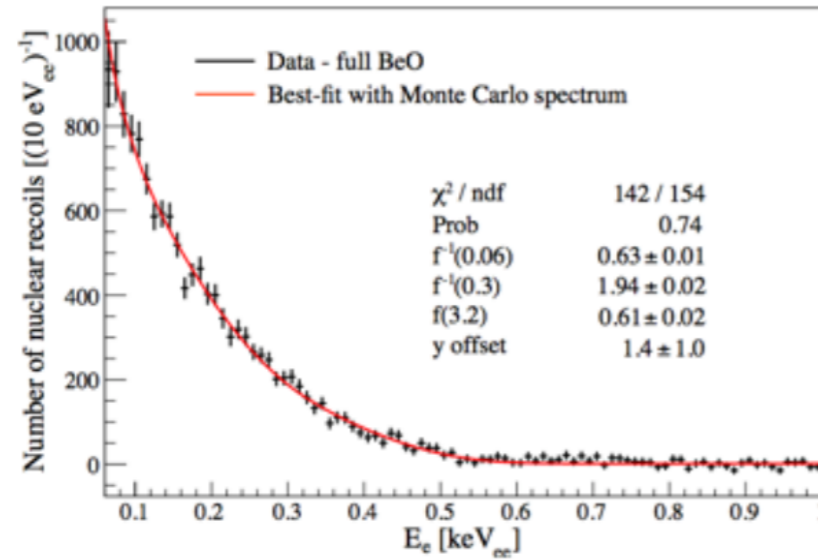

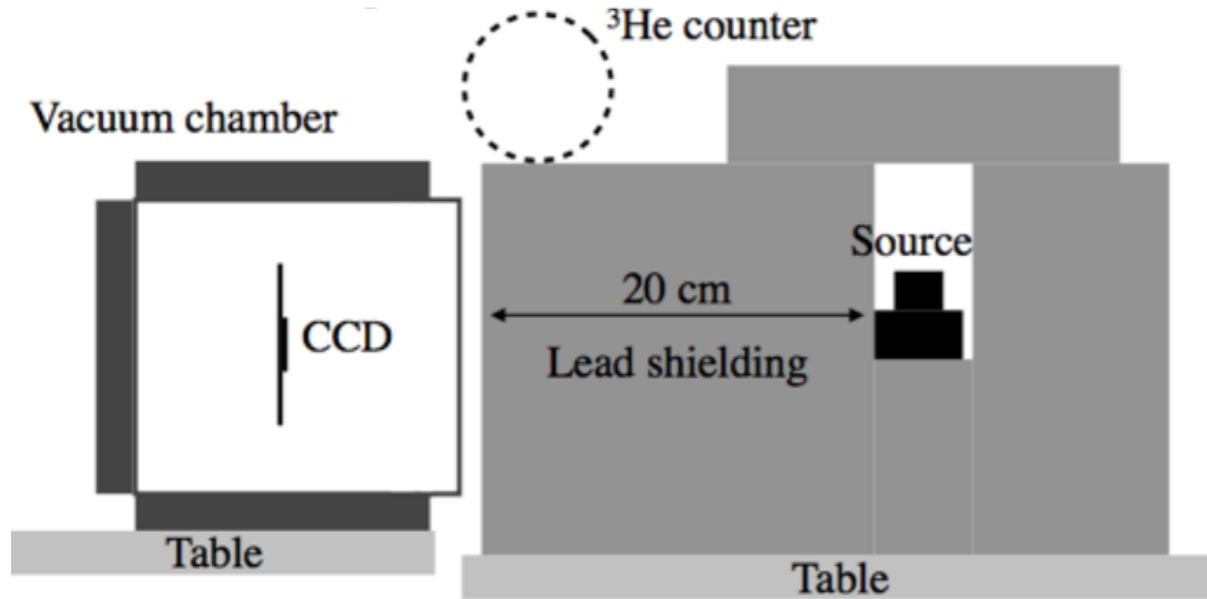

FIG. 4. Ionization spectrum of nuclear recoils induced by neutrons from the full BeO target source (black markers) and best fit to the data (solid line). The fitting function was obtained by applying a cubic spline model f of the nuclear recoil ionization efficiency to the simulated recoil spectrum and convolving with the detector energy resolution. The best-fit parameters of the spline are given in the legend.

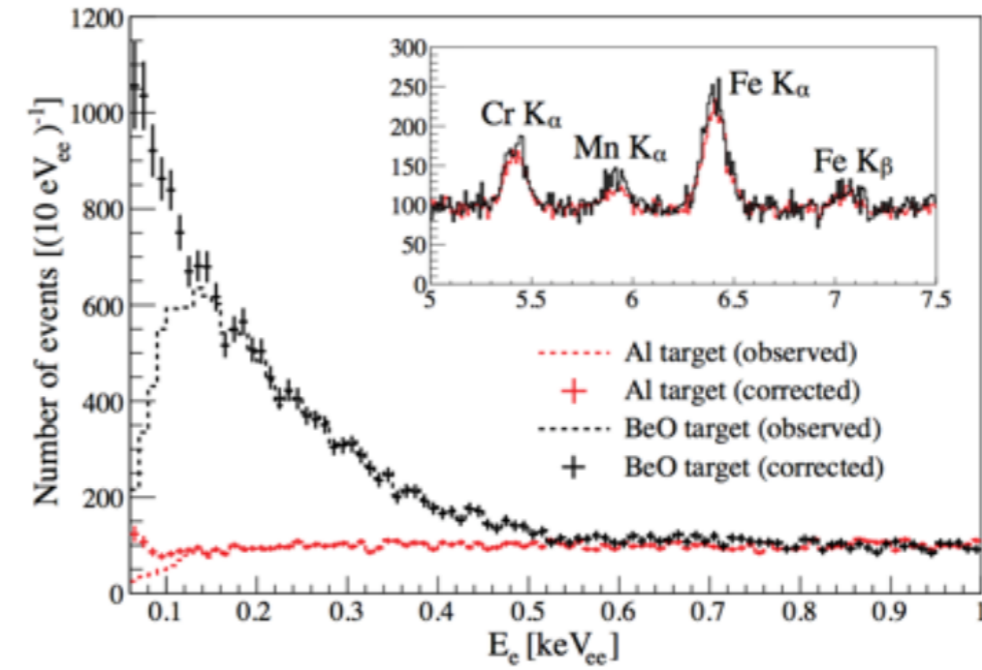

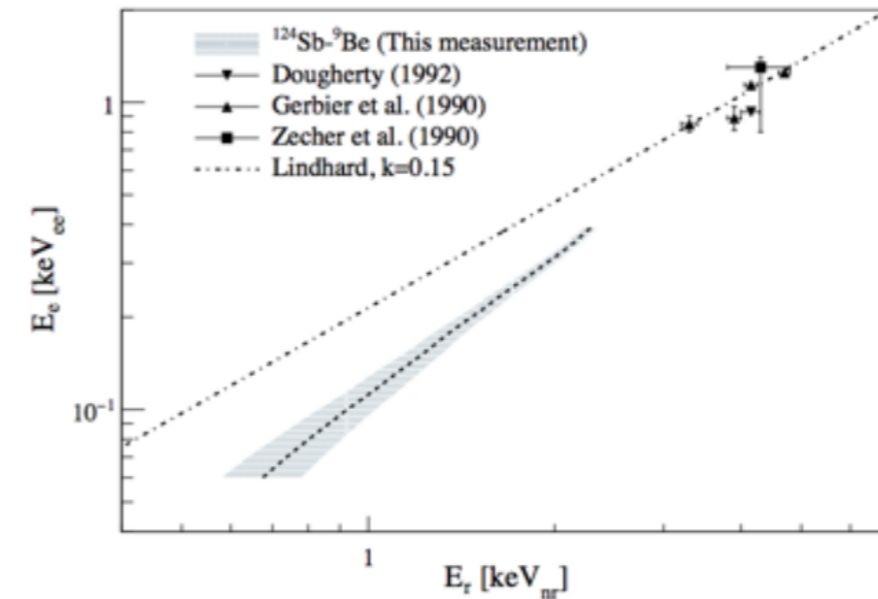

FIG. 2. Measured ionization spectra with the full BeO and Al targets (dashed lines). Solid markers represent the spectra corrected for the energy-dependent event selection acceptance. The inset shows the spectra in the 5.0–7.5 keV_{ee} range, with in-run calibration lines from fluorescence x rays originating in the stainless steel of the vacuum chamber.

CONNIE rates

Energy spectra in silicon detectors

Phys.Rev. D 91, 072001 (2015)

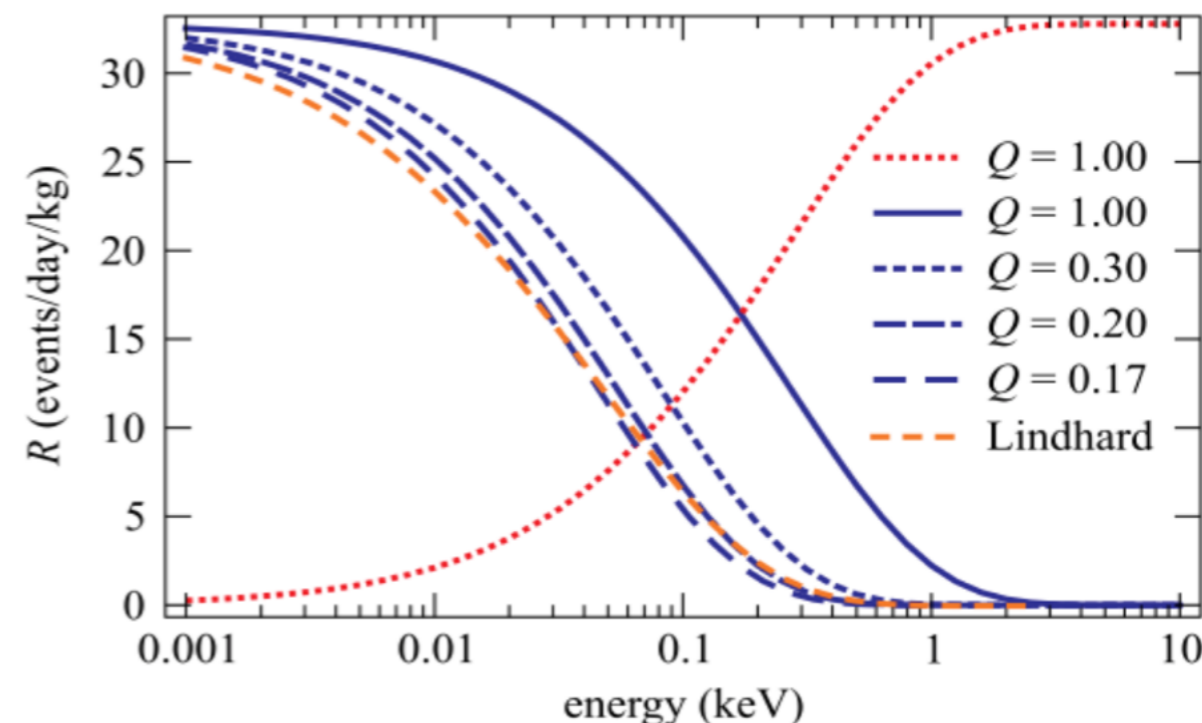

$$Q = 0.20$$

Expected number of events (event/kg/day)

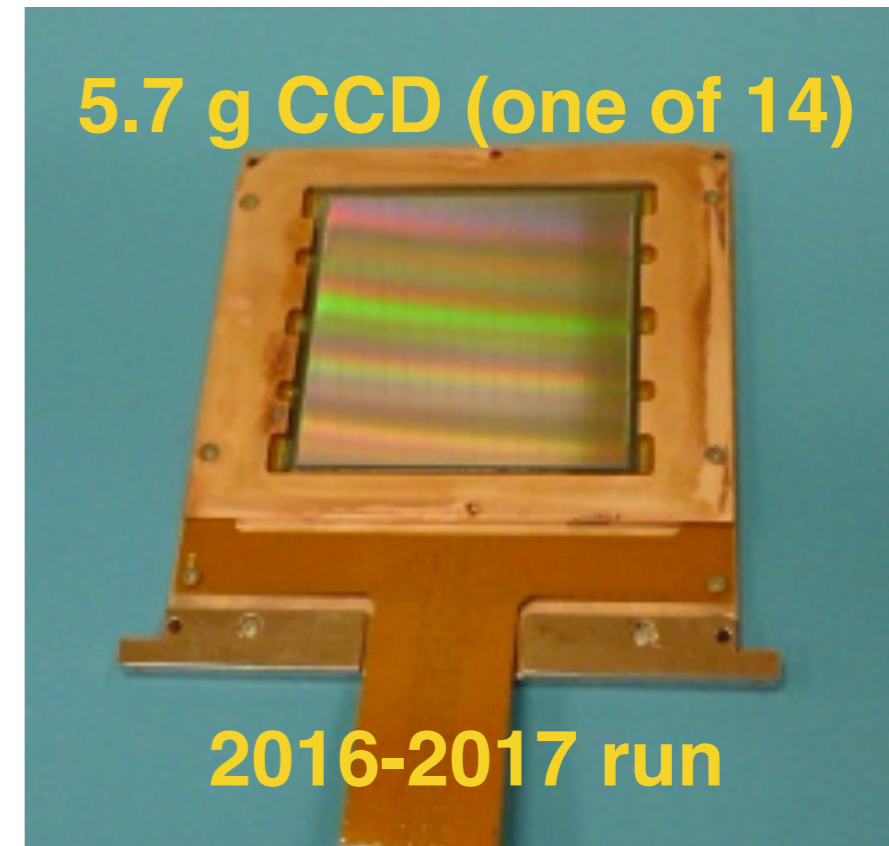

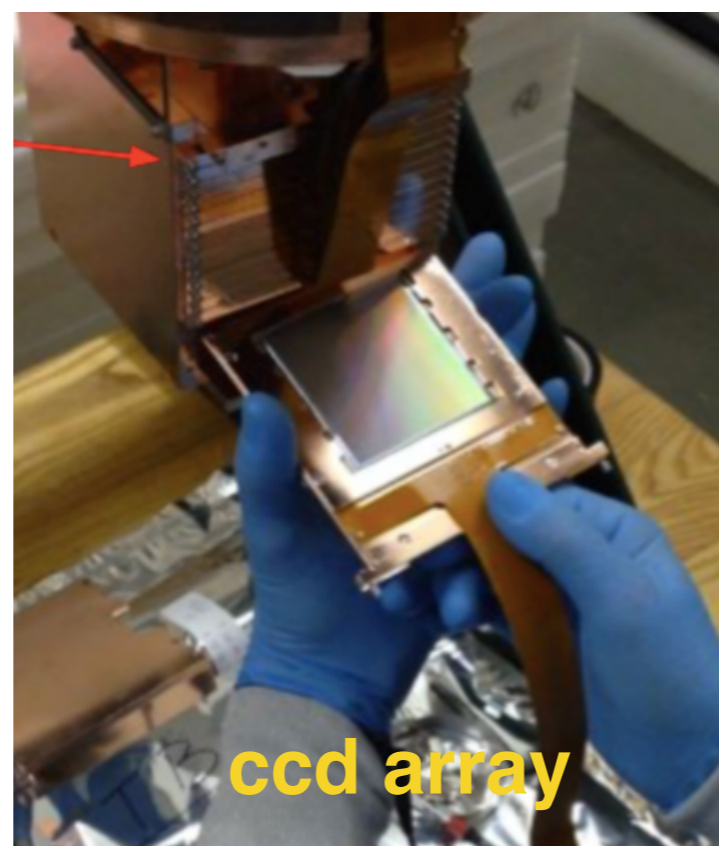

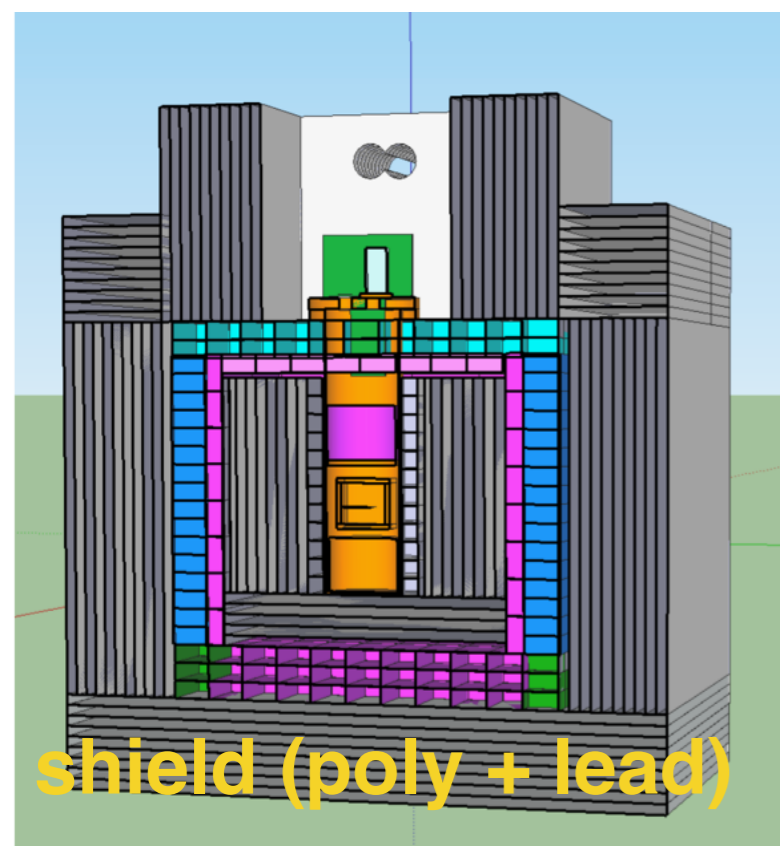

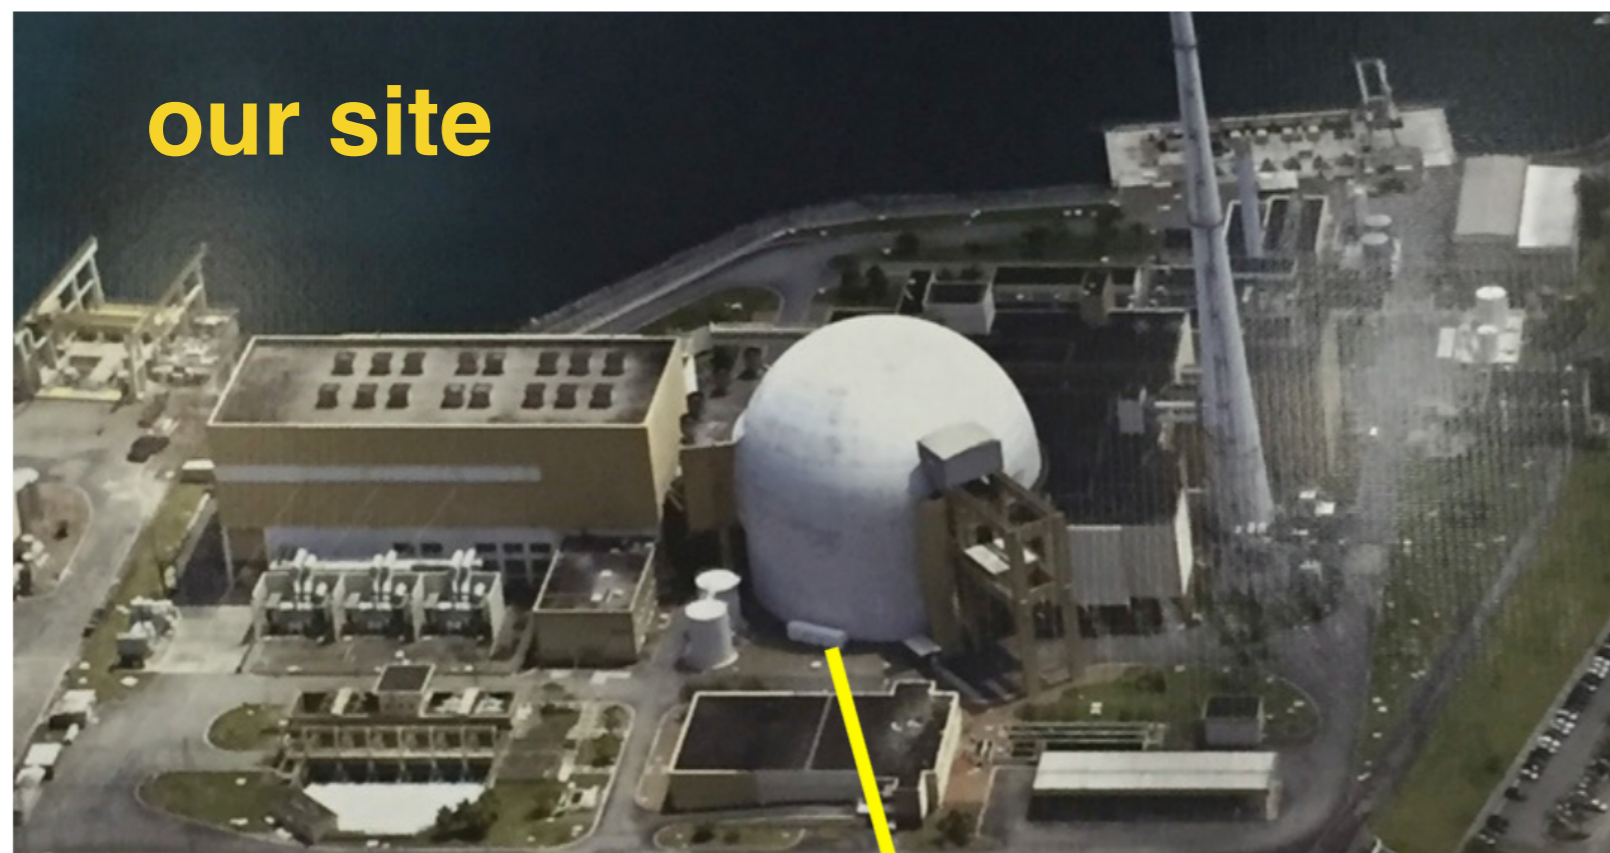

$$E_{\text{th}} = 5.5 \text{ eV } (1\sigma_{\text{RMS}}) \quad \sim 28.3$$

$$E_{\text{th}} = 28 \text{ eV } (5\sigma_{\text{RMS}}) \quad \sim 18.1$$

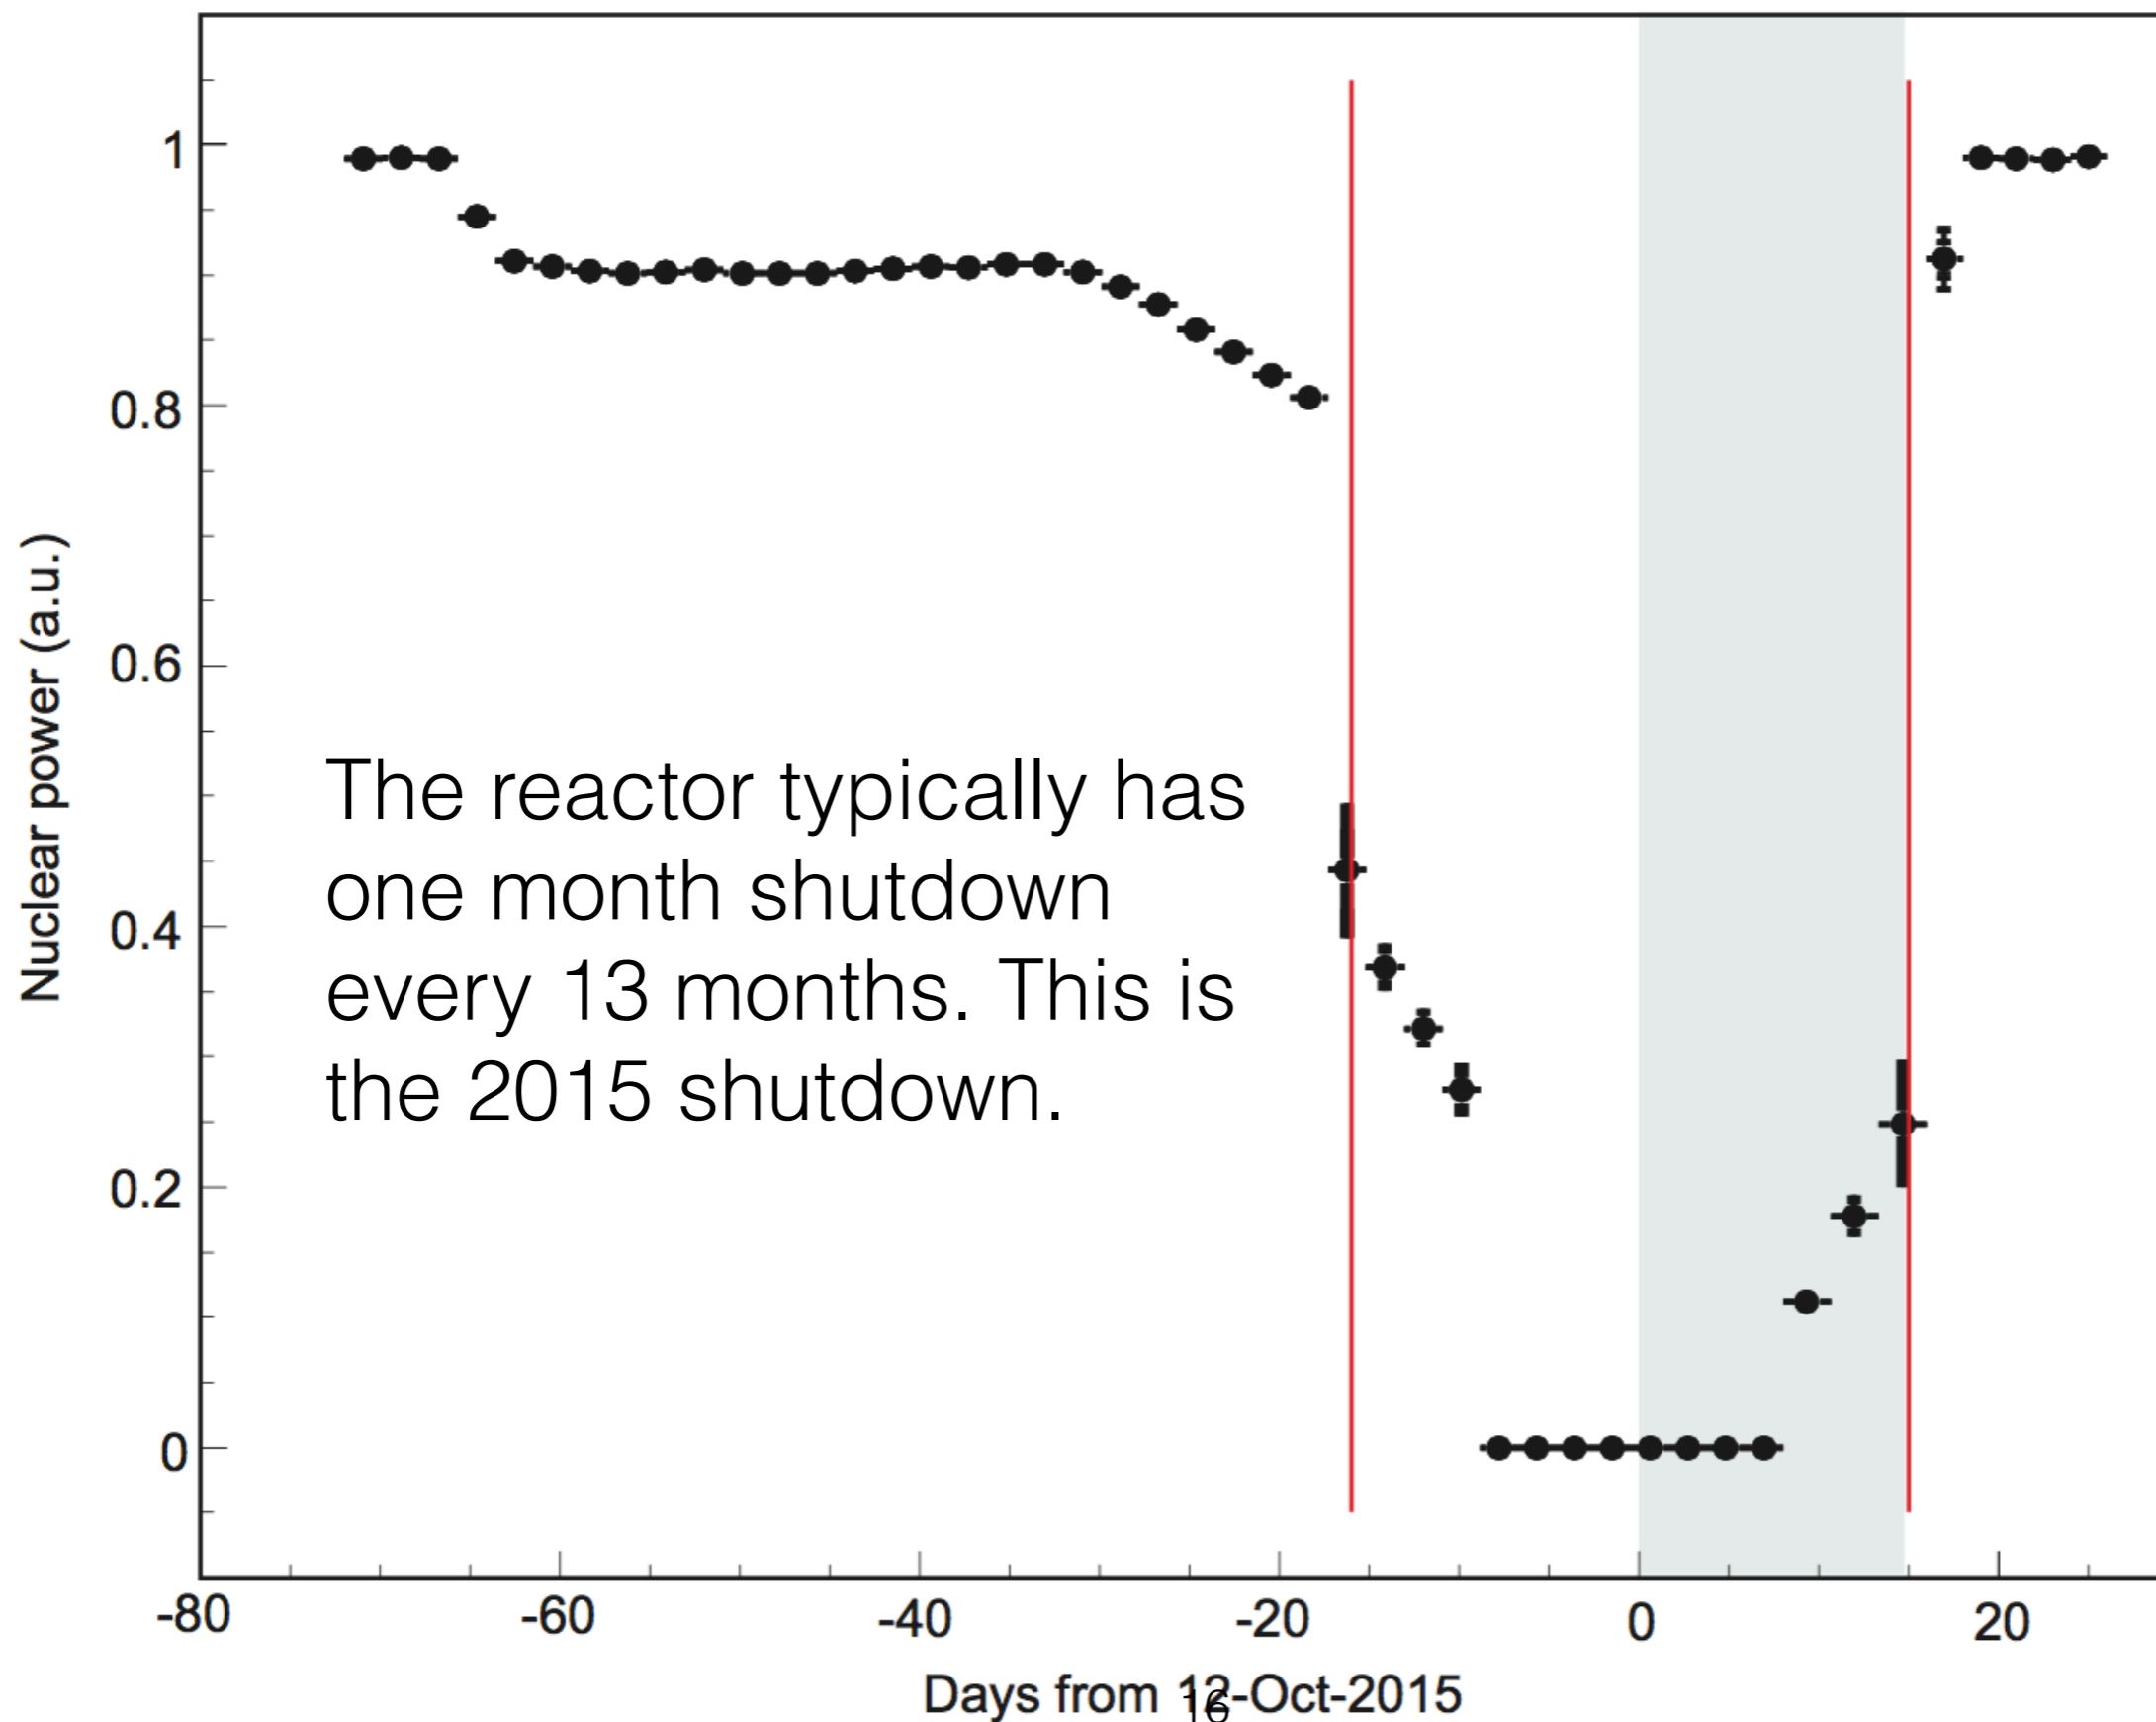

Total number of events vs threshold energy for different quenching factors

Total events vs max. detectable recoil for $Q=1$

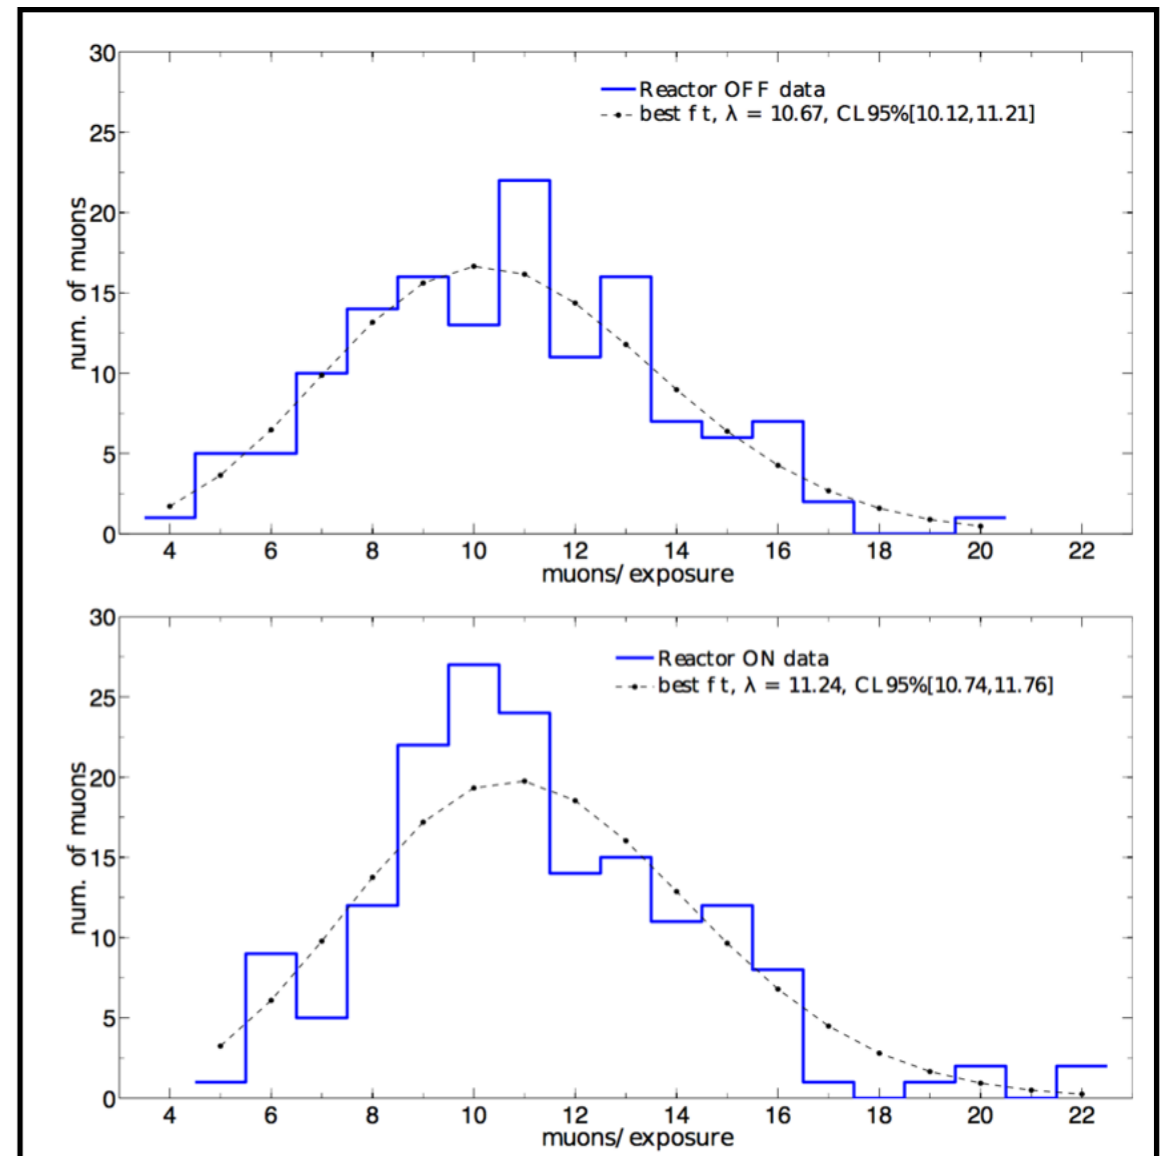

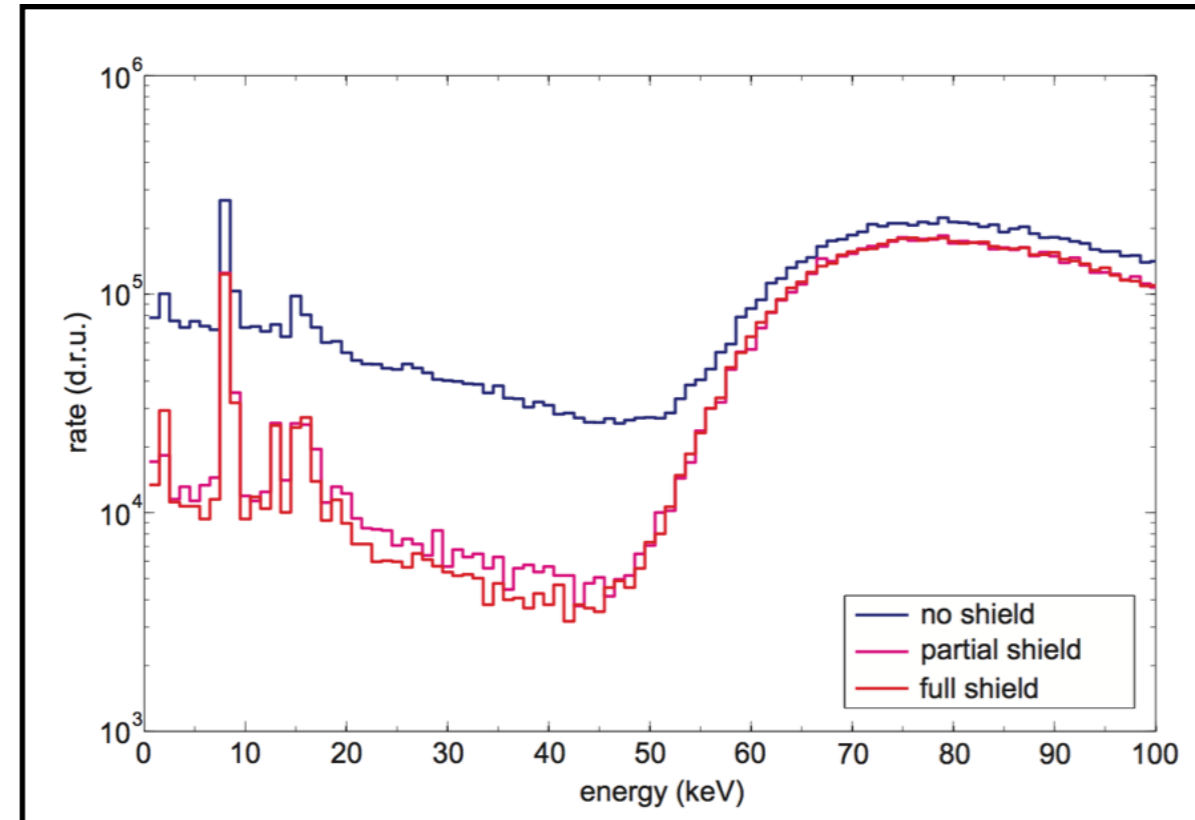

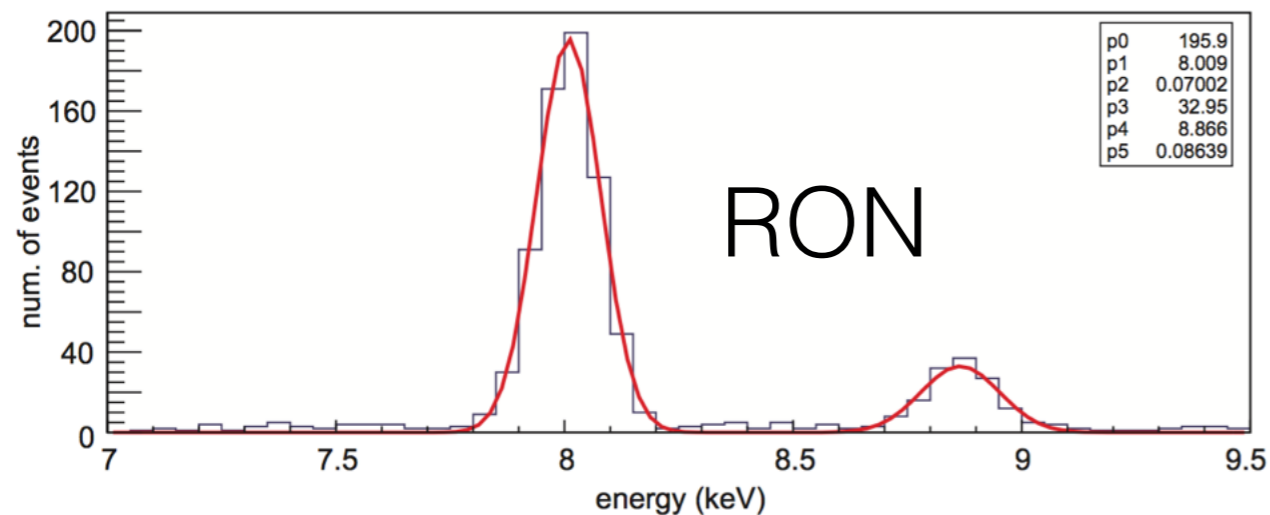

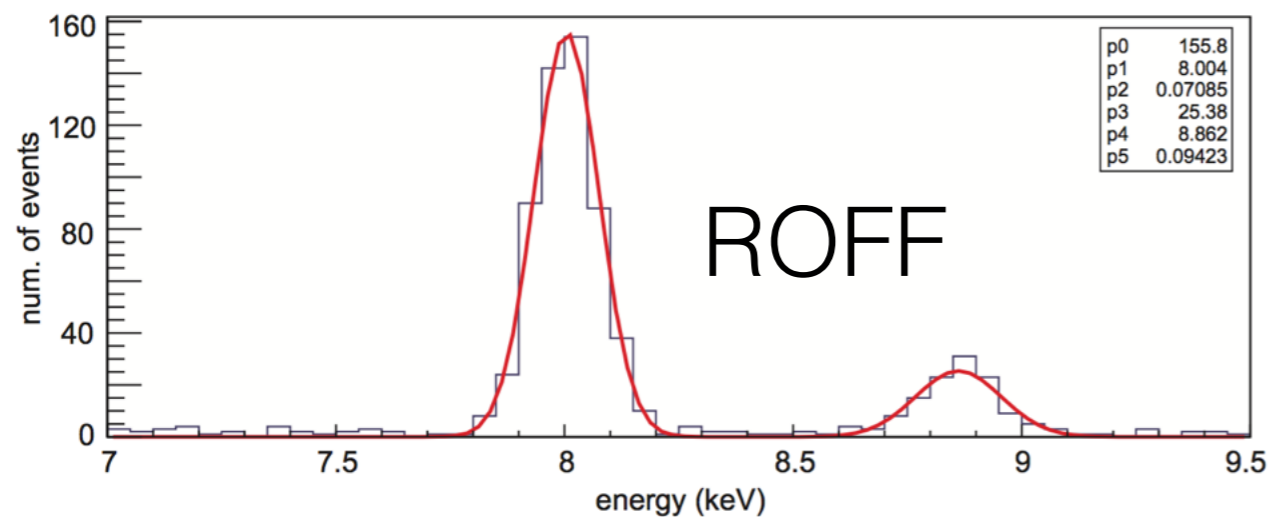

2015 Engineering Run

2015 engineering run FNAL-LDRD program (1g active mass, 1 CCD)

Reactor	counts (7.8-8.2 keV)	exposure (day)	rate (counts/day)
RON	693	18.0	38.5 ± 1.46
ROFF	557	14.8	37.6 ± 1.61

2015 : no excess

2D event modeling (Likelihood)

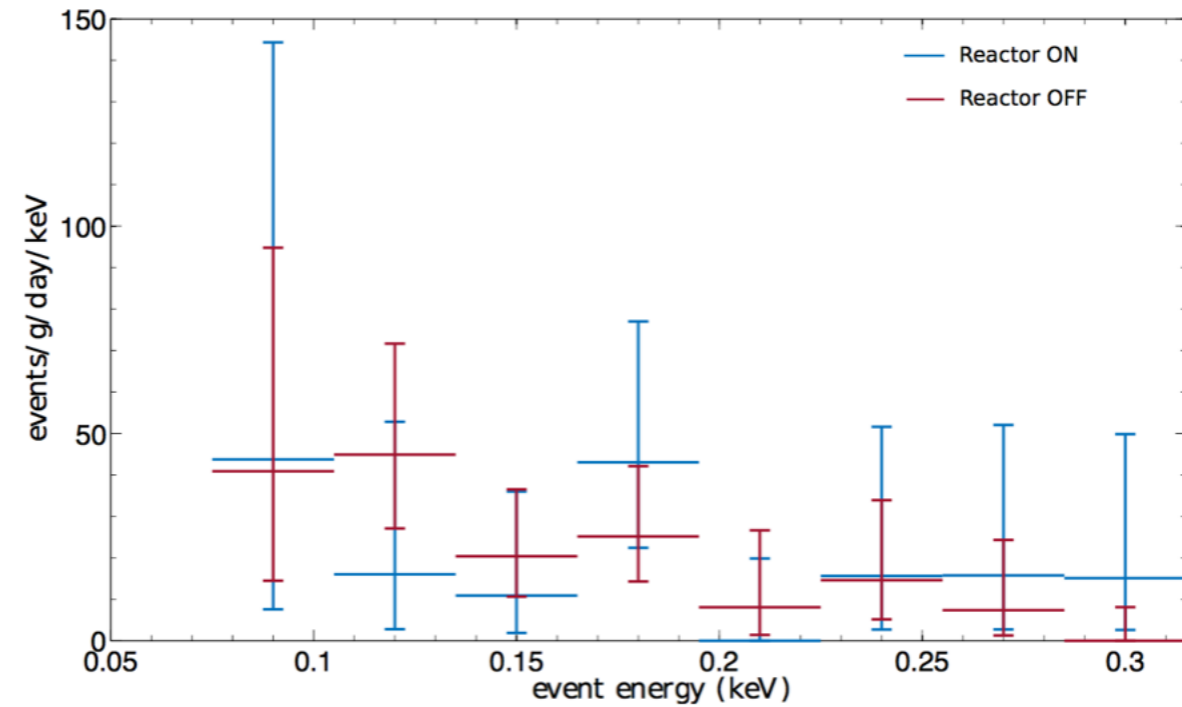

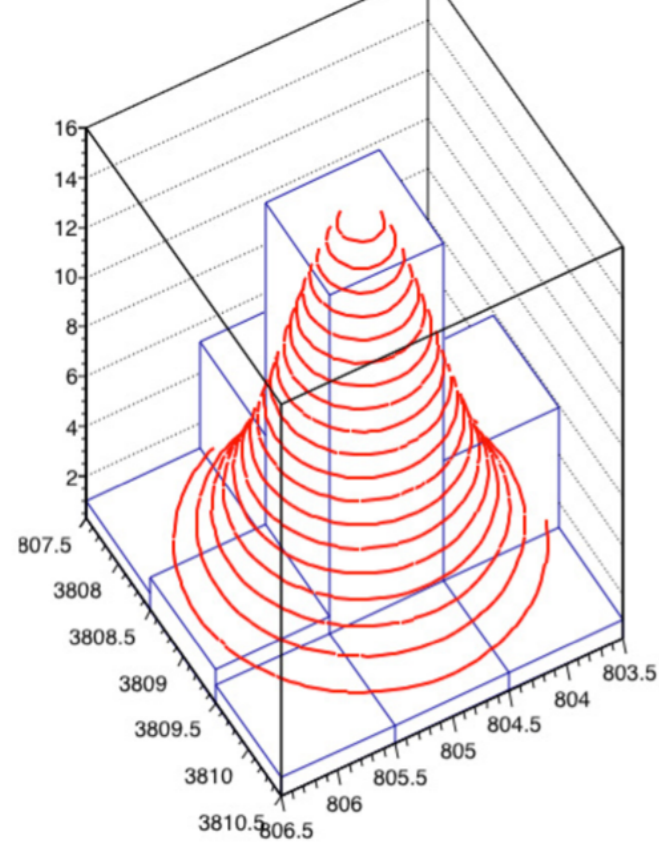

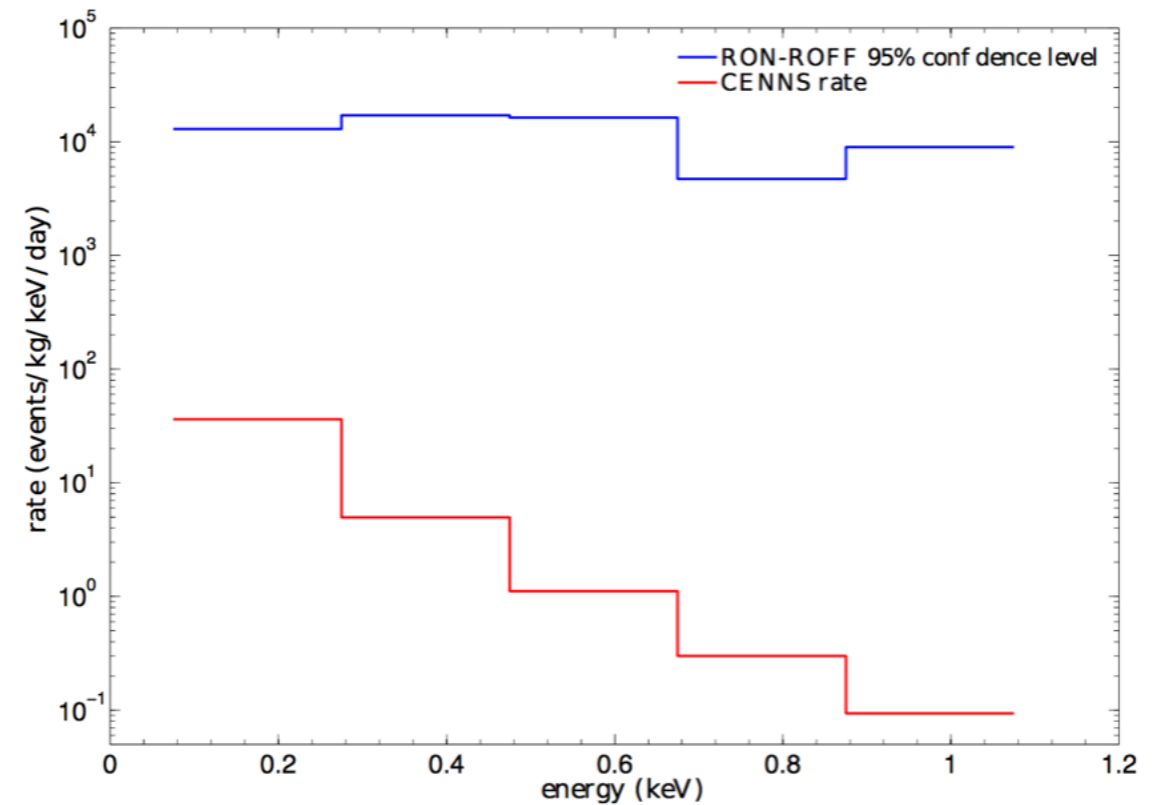

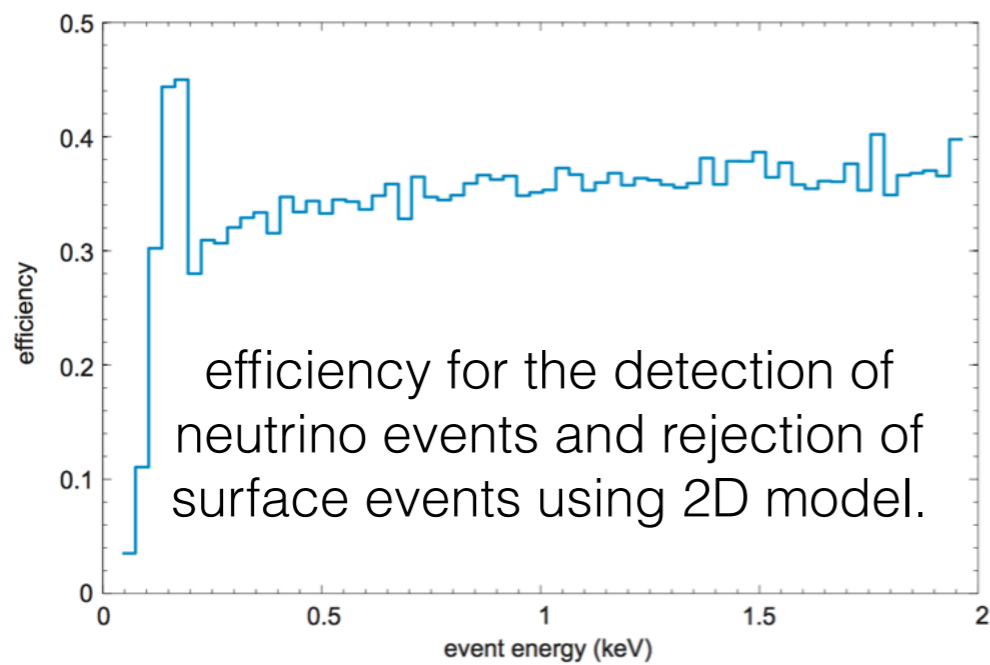

Figure 17: Same as Fig.16, the error bars correspond to 68.27% probability assuming a Poisson distribution for each energy bin.

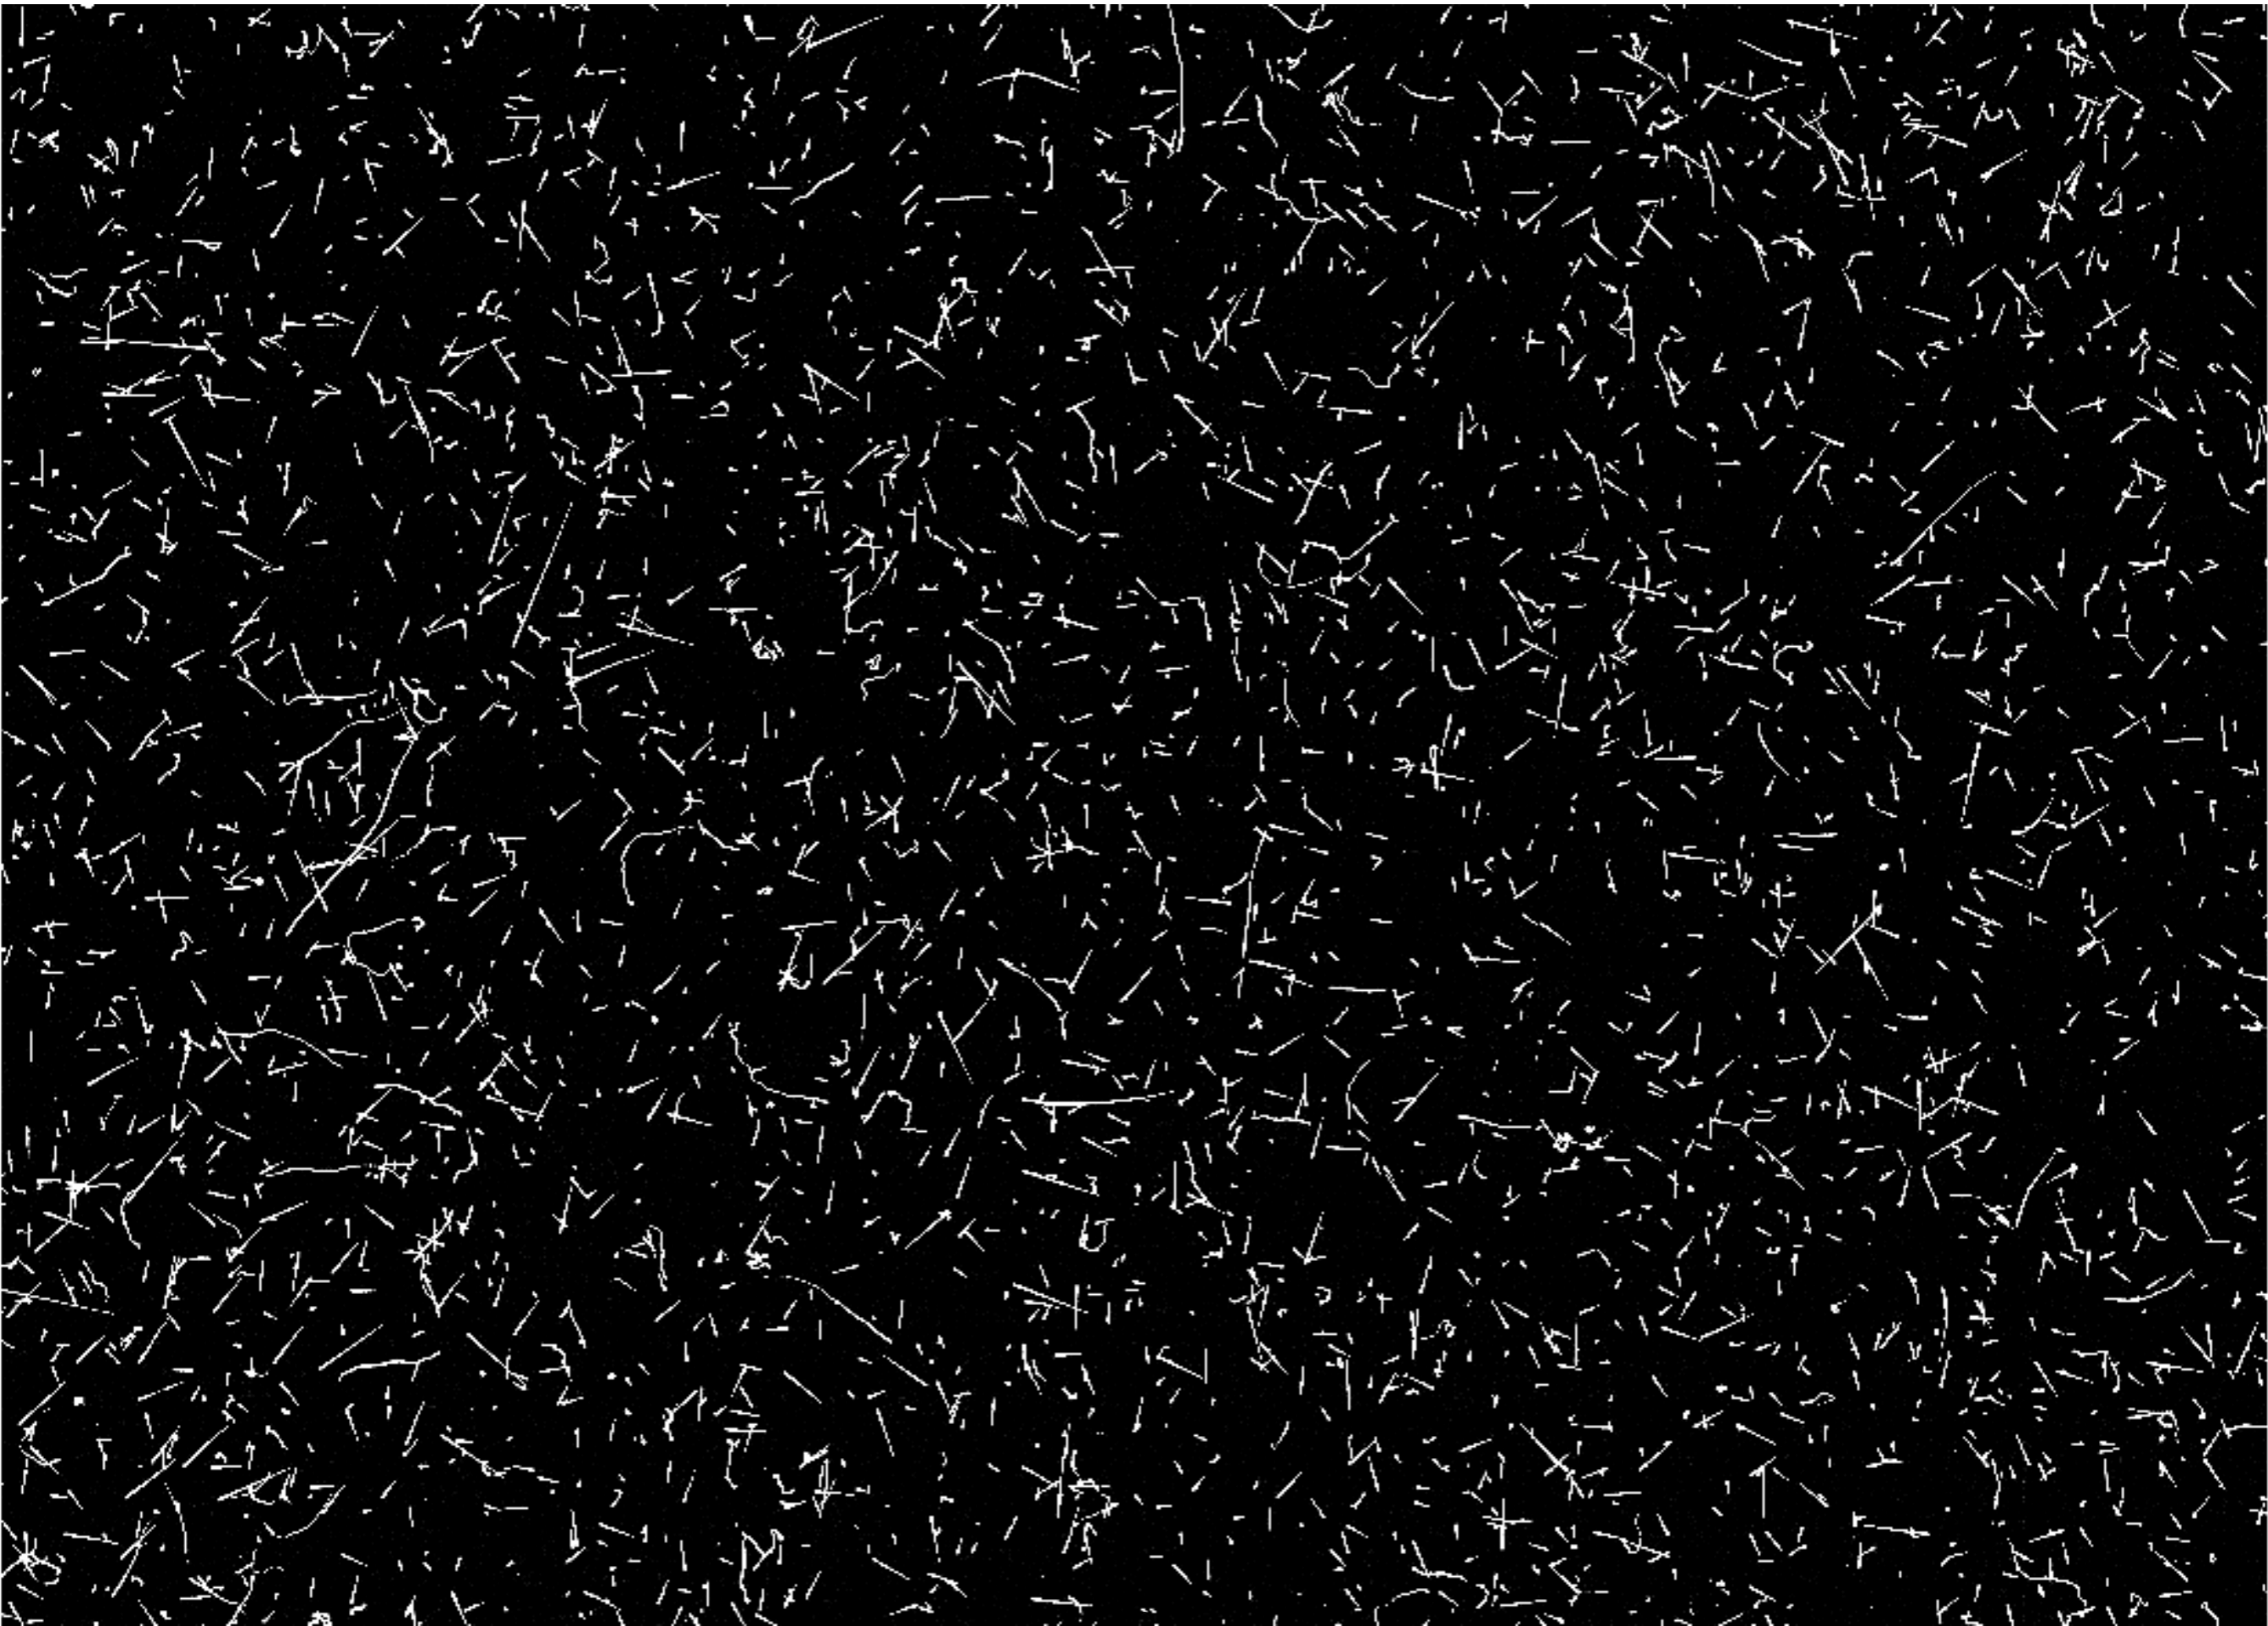

2016

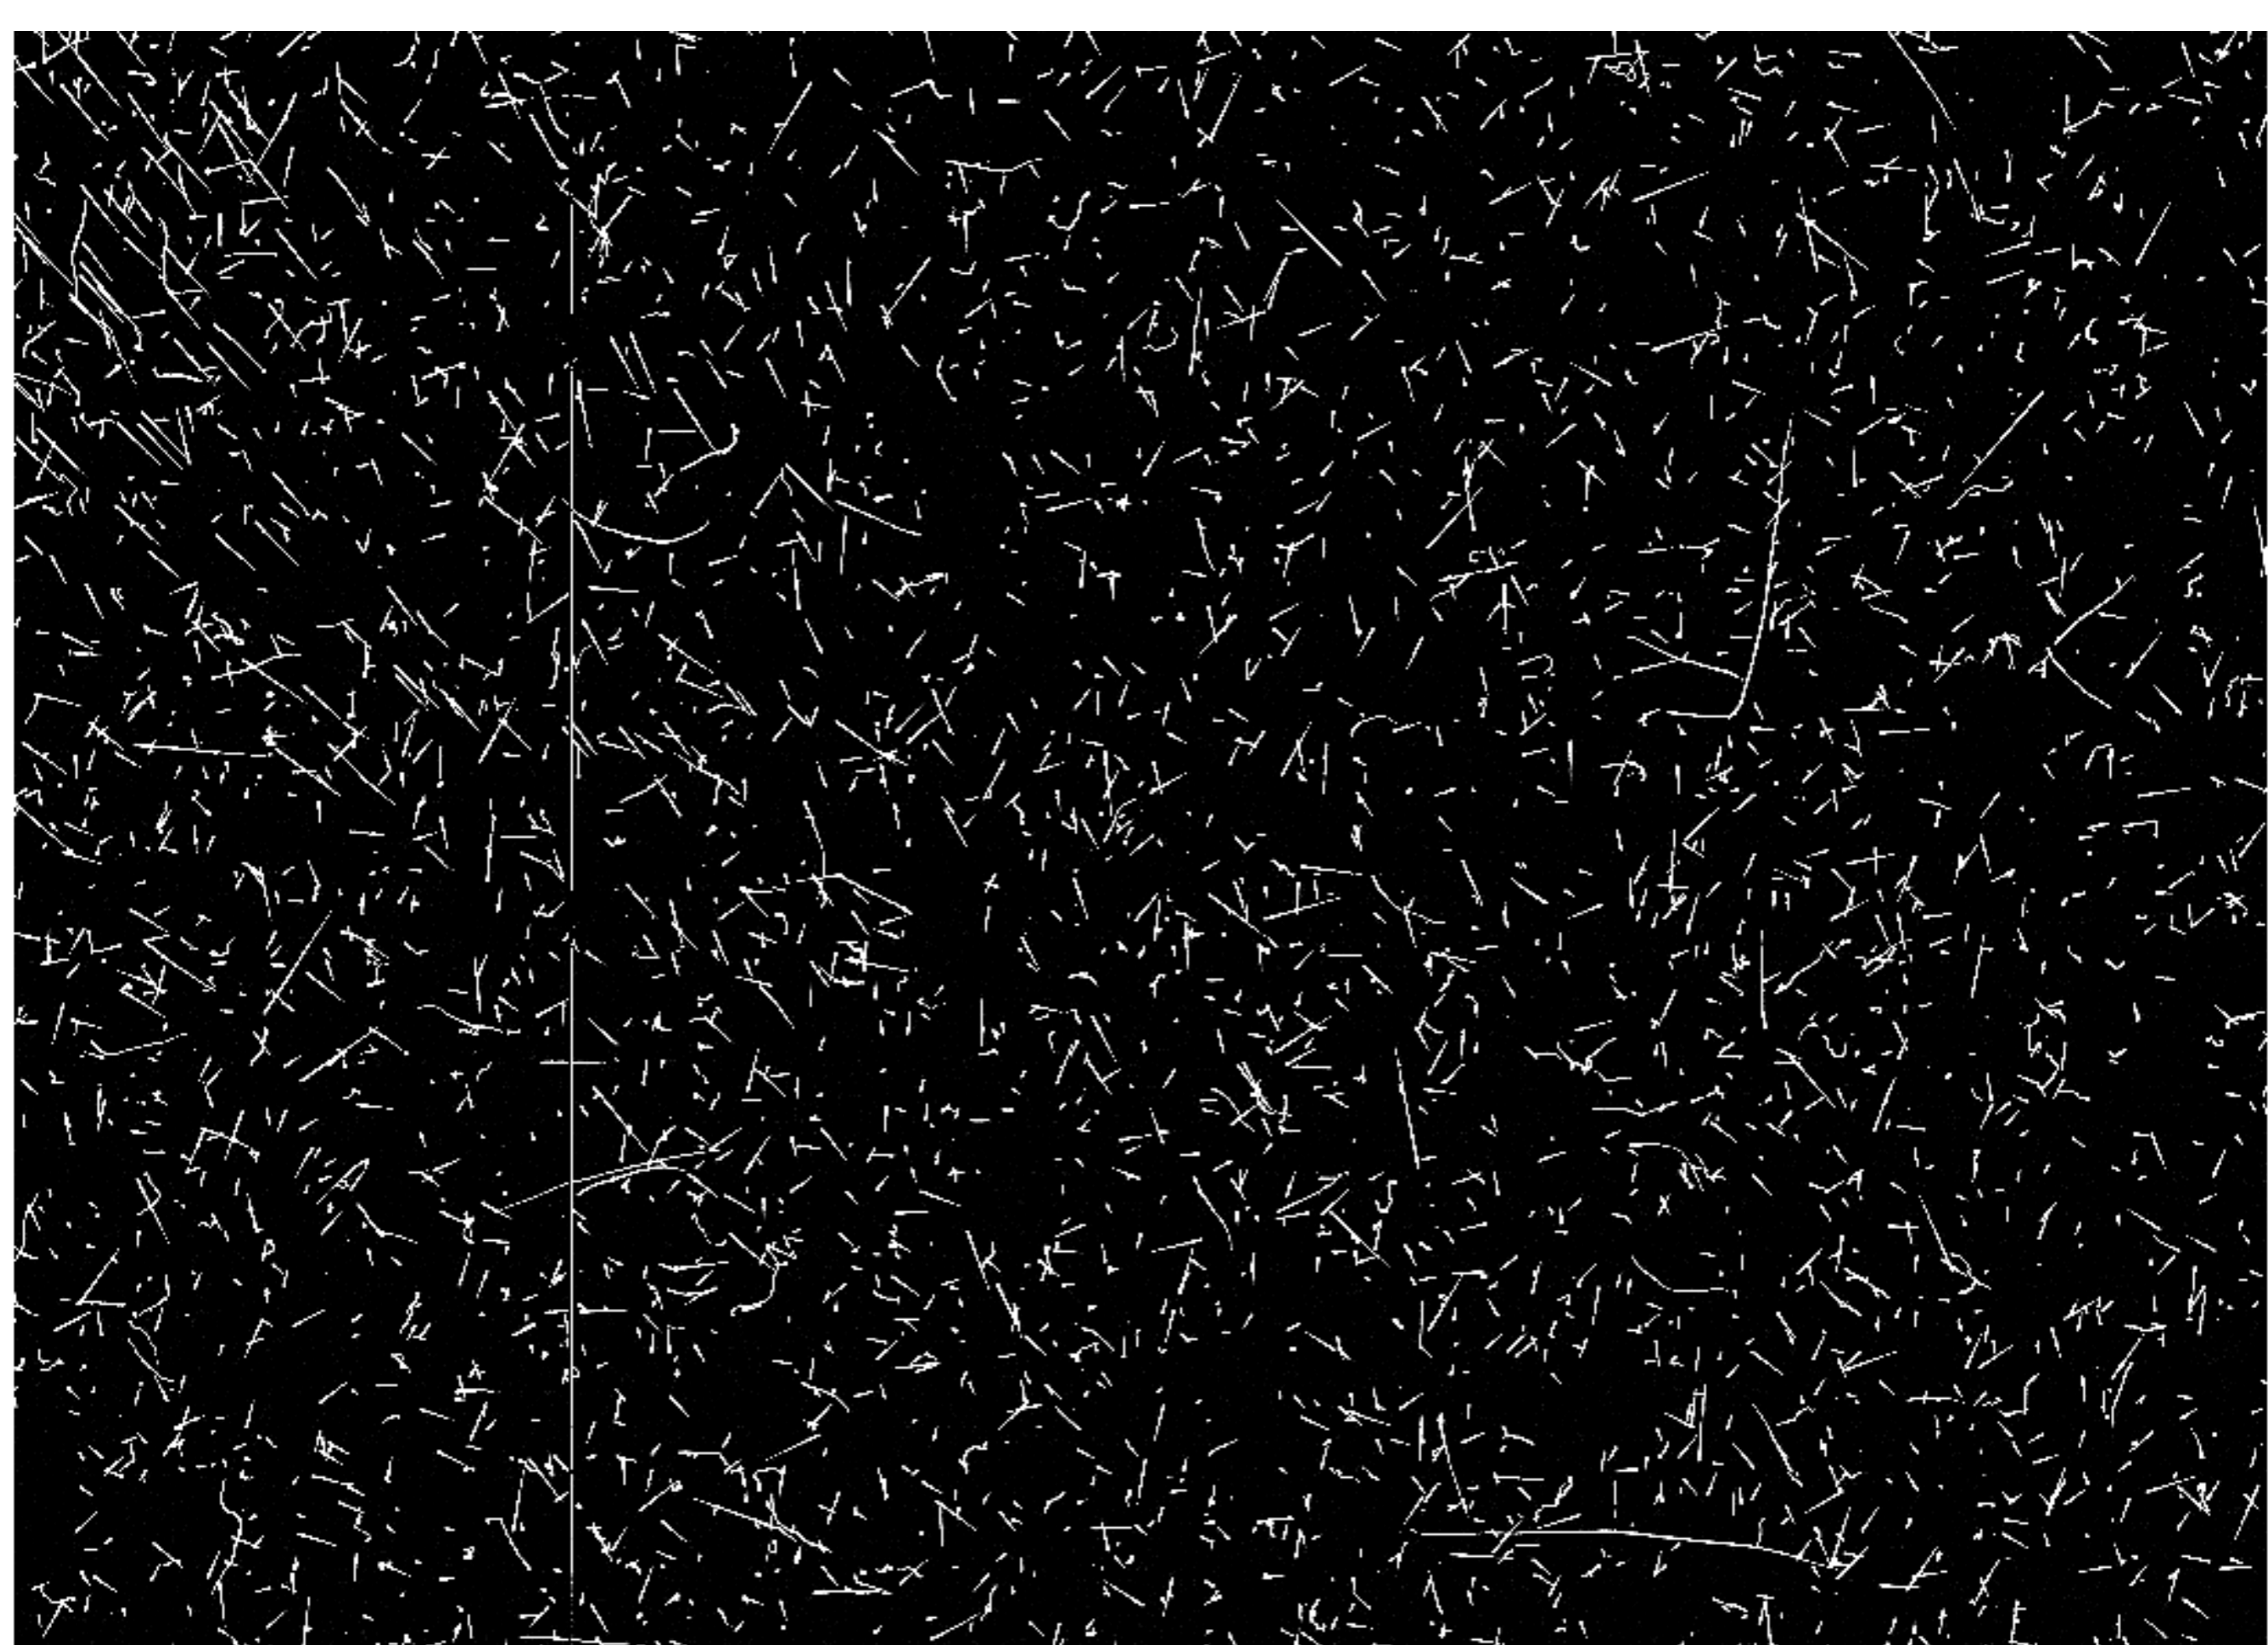

- Exposure increase x 130:

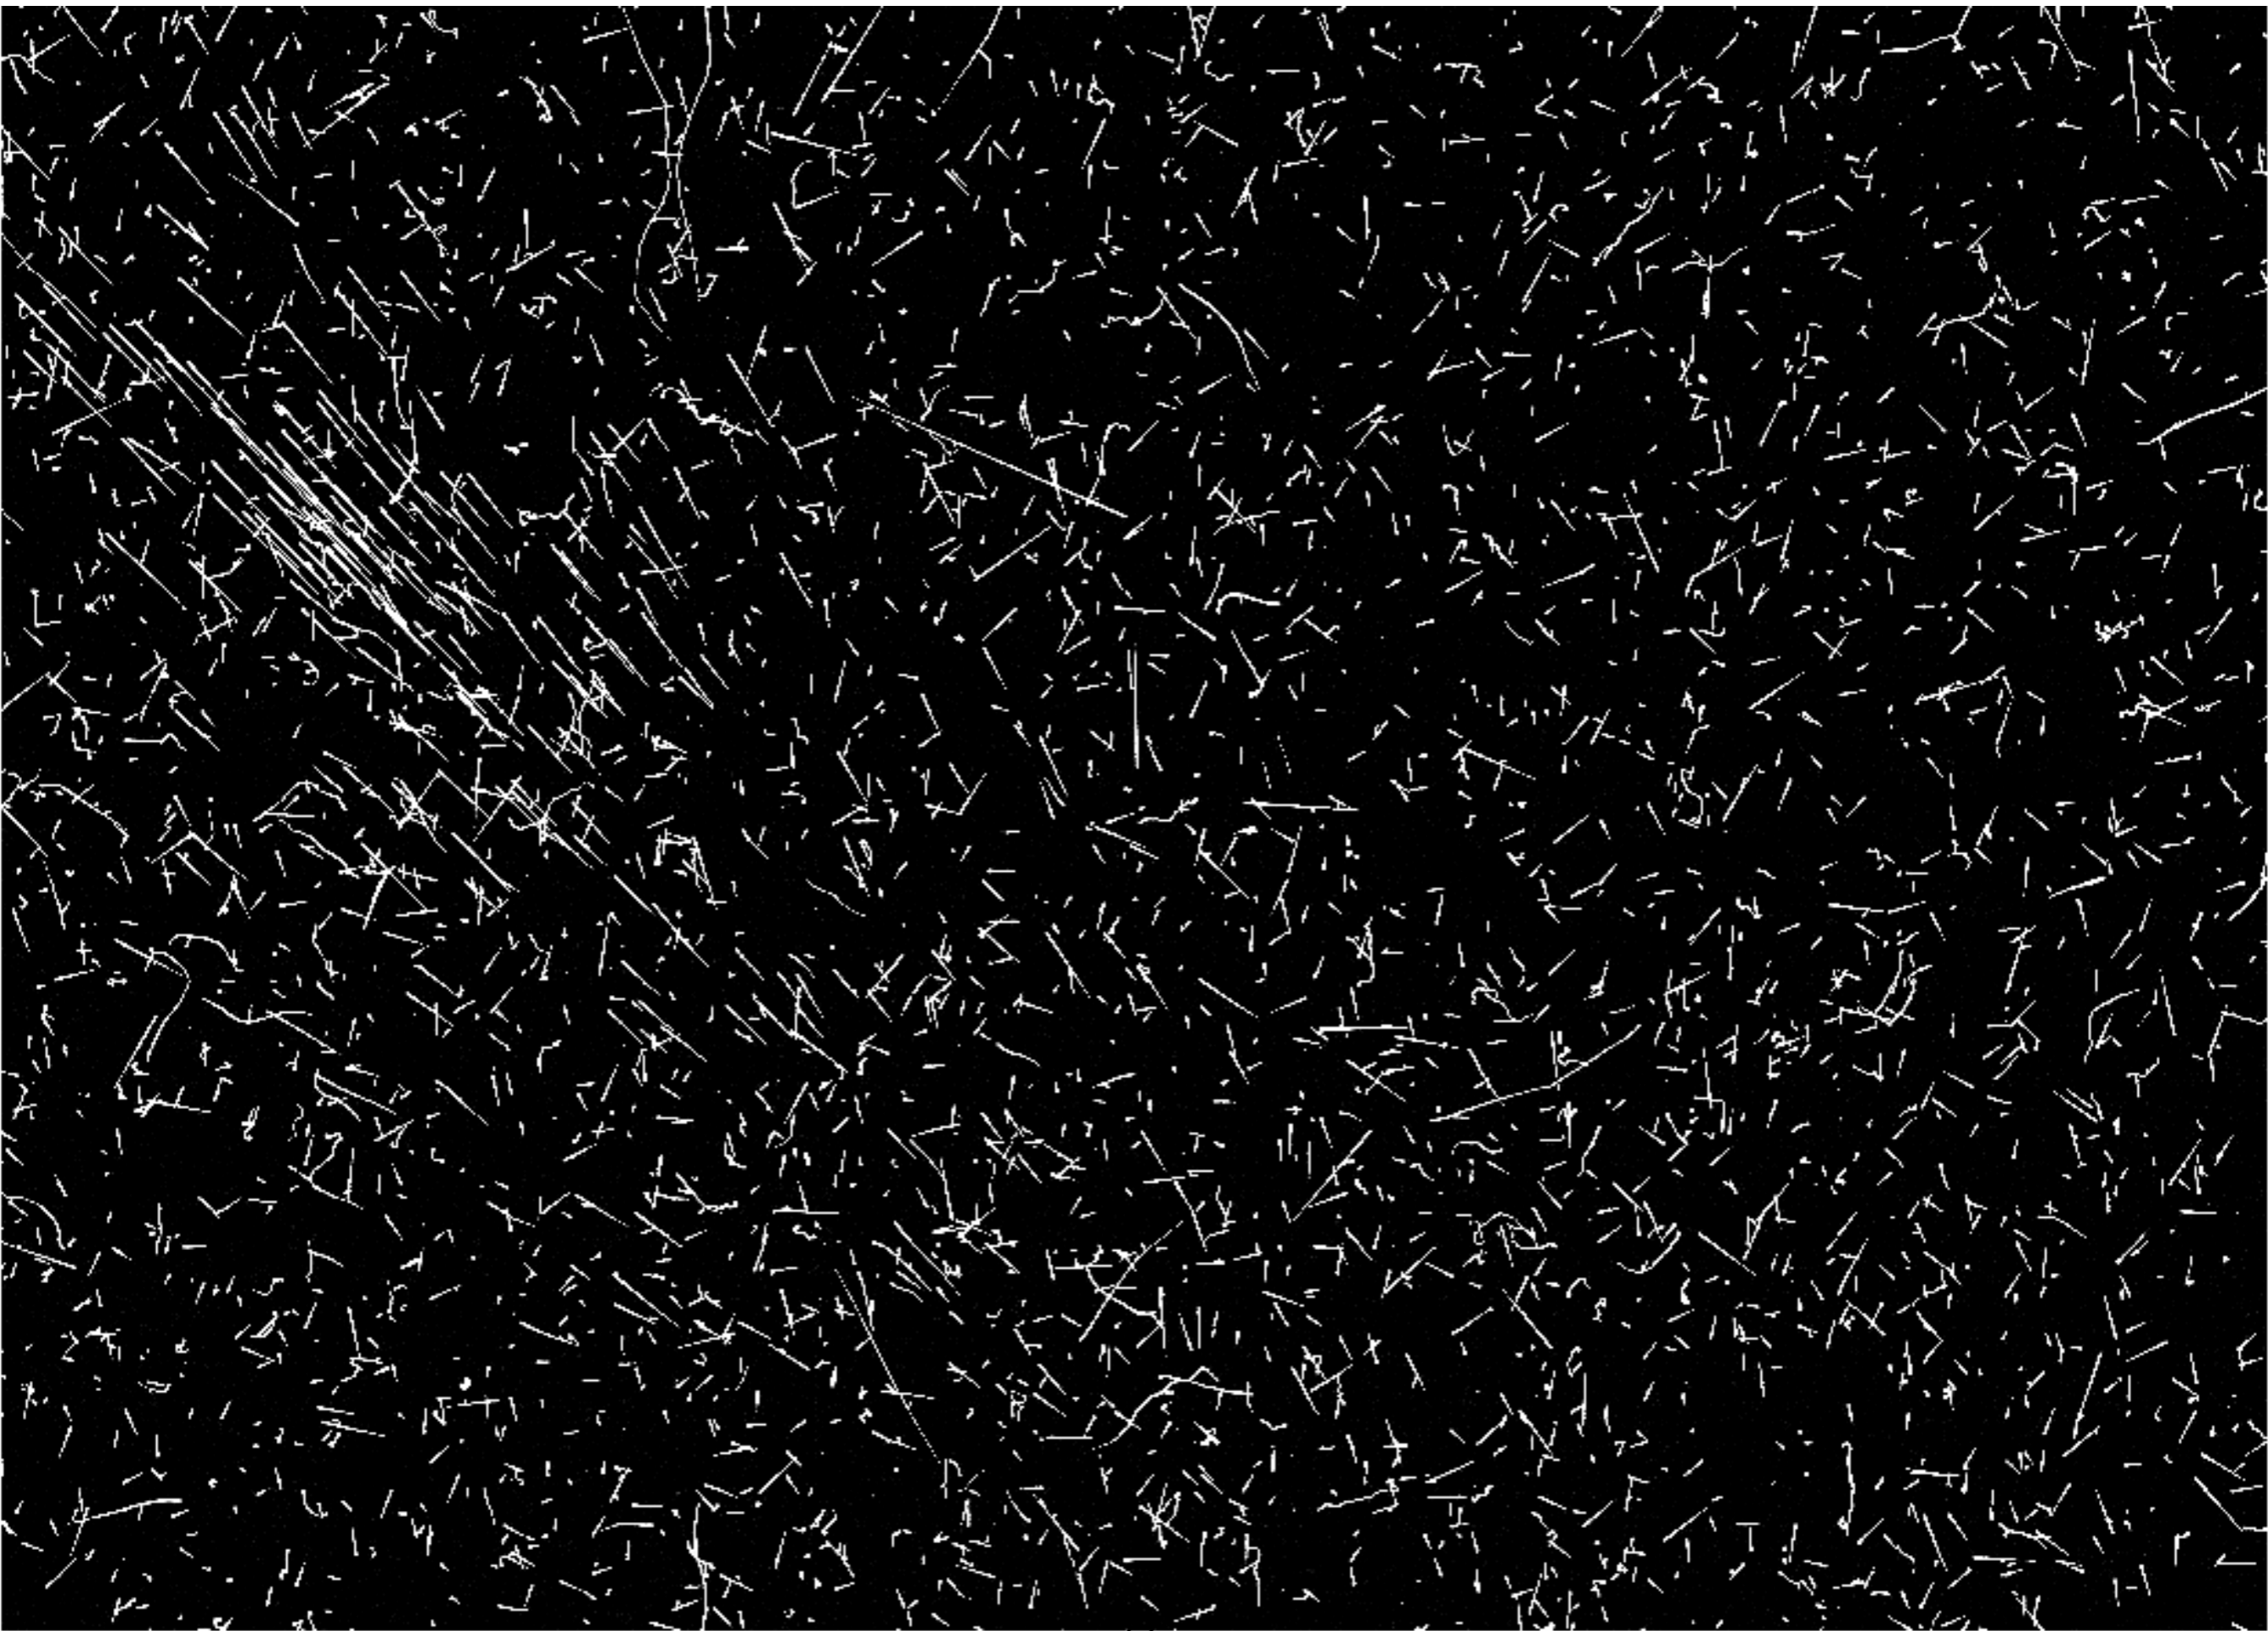

Reactor OFF exposure 1.9 kg-day (30 days x 80 g x 0.8 eff)
compared to 15 d-day in 2015.

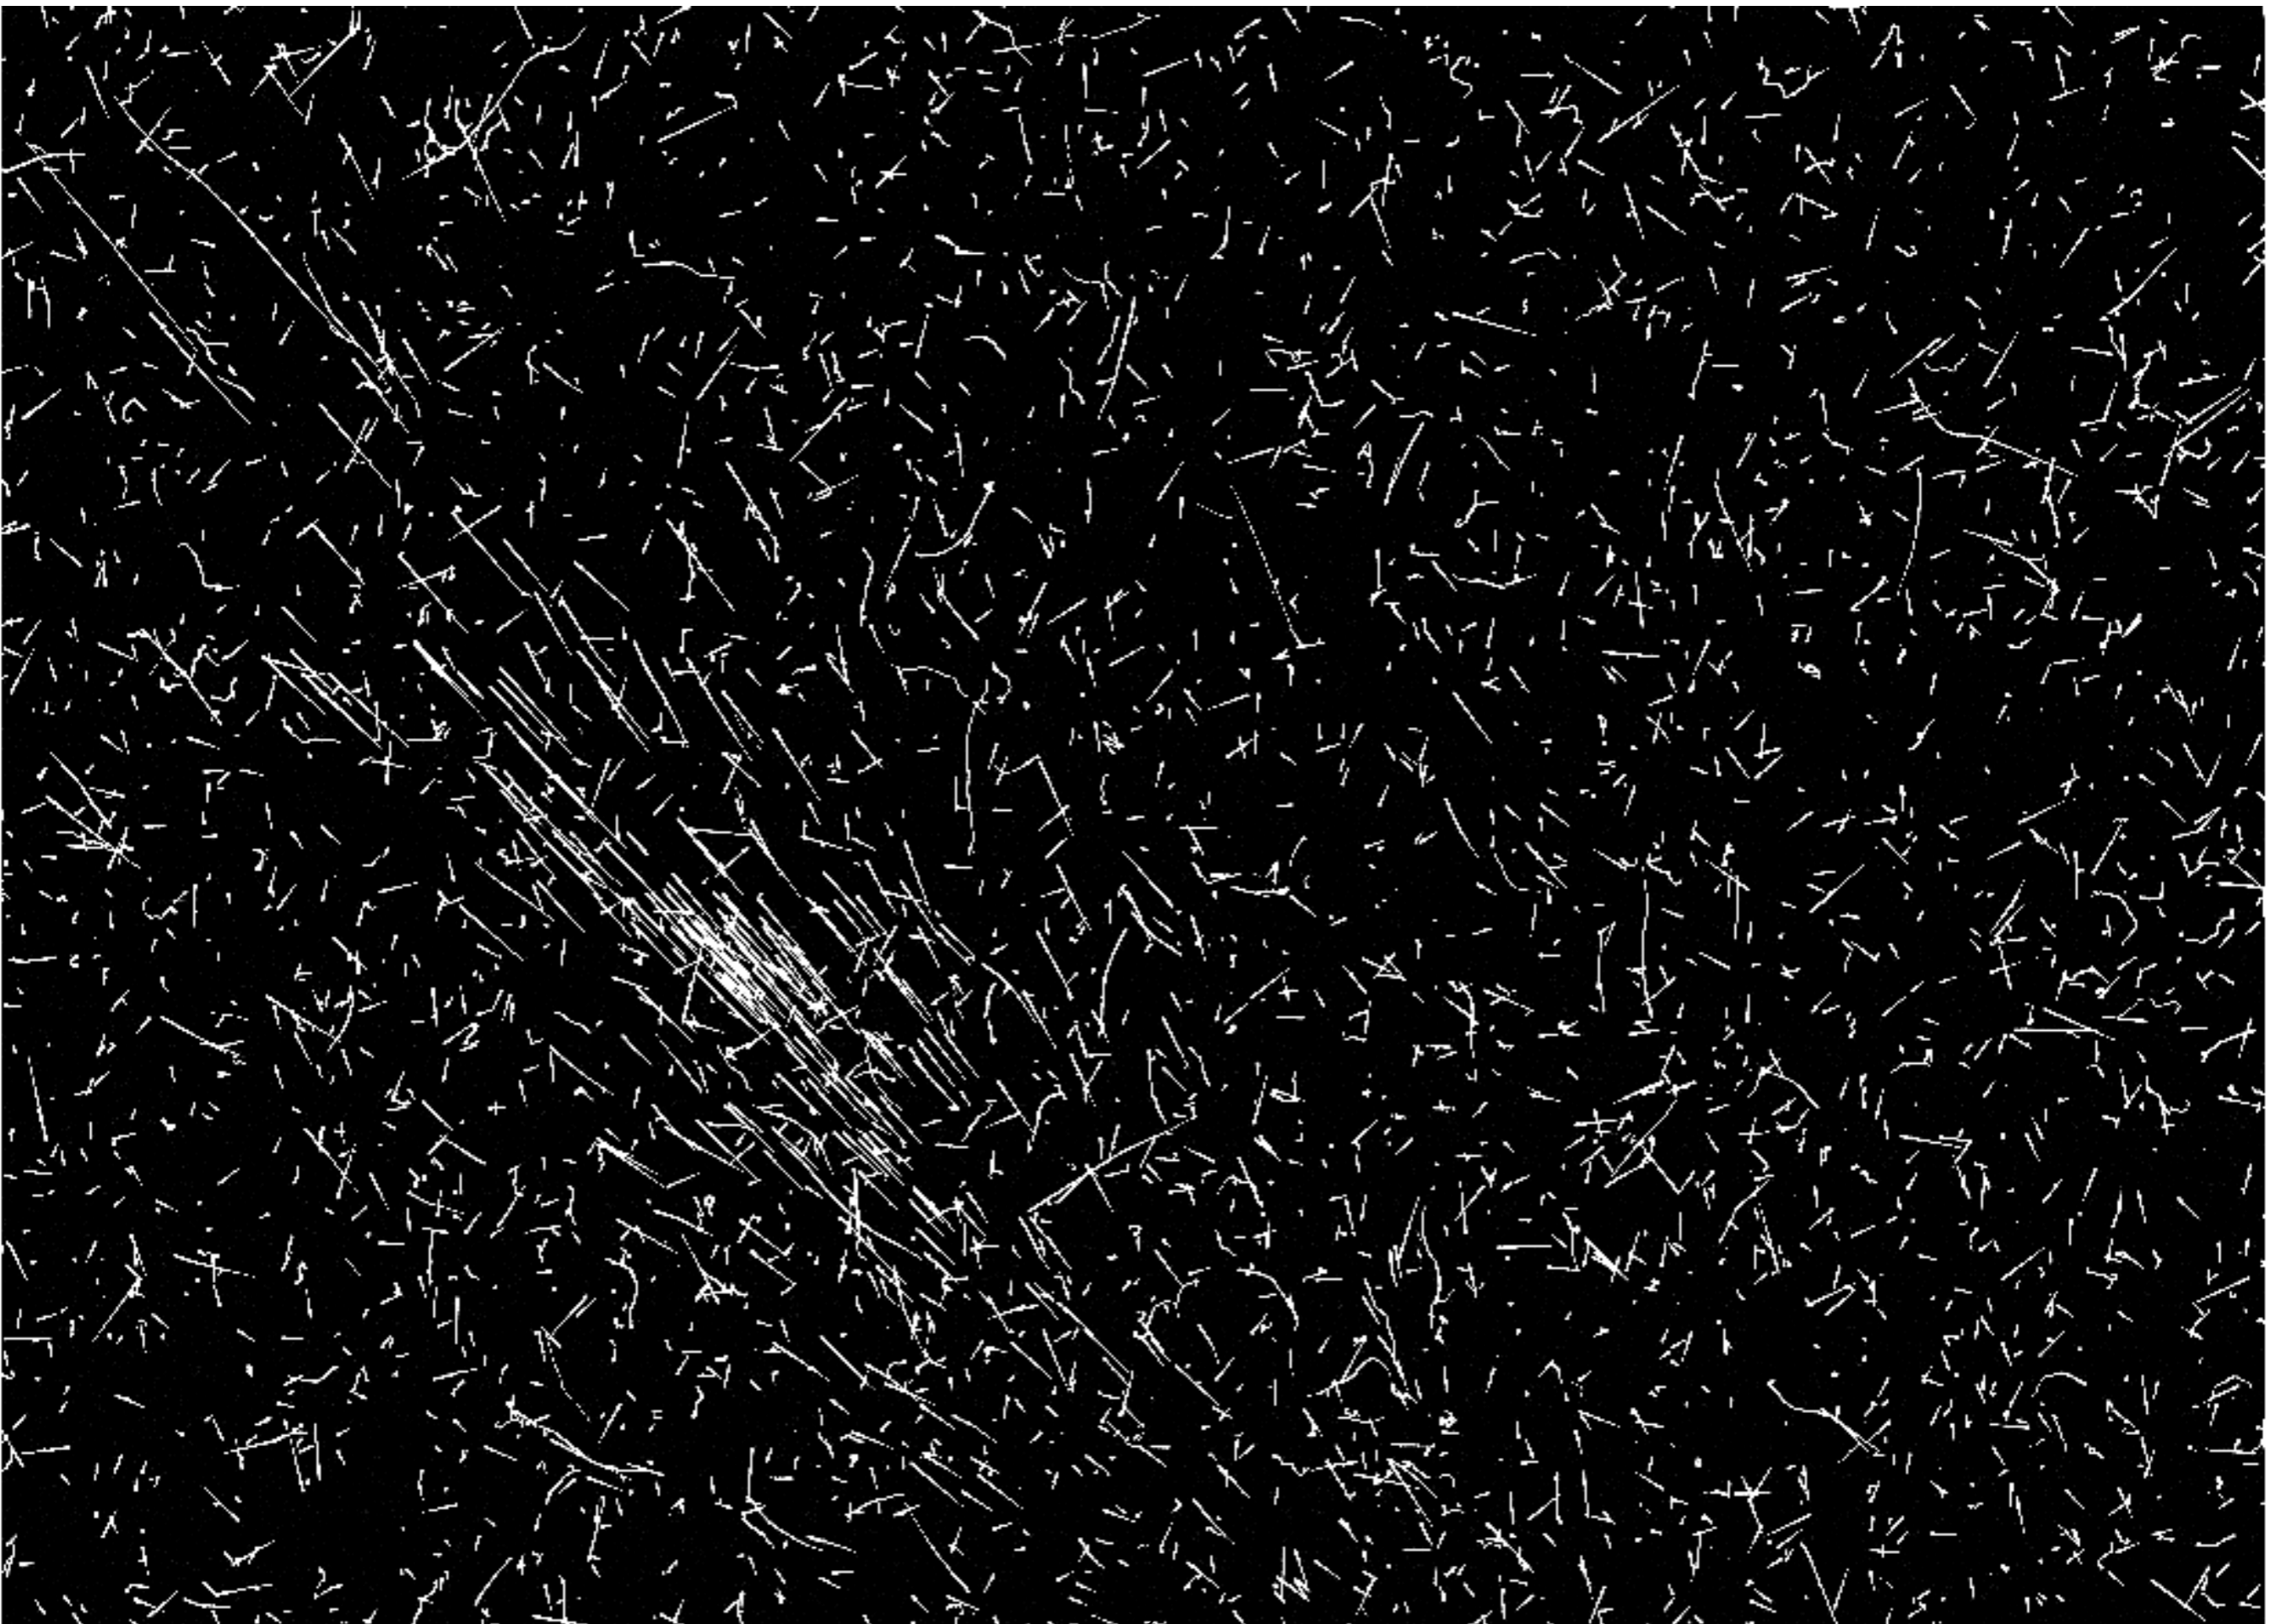

- Lower noise
- Lower background

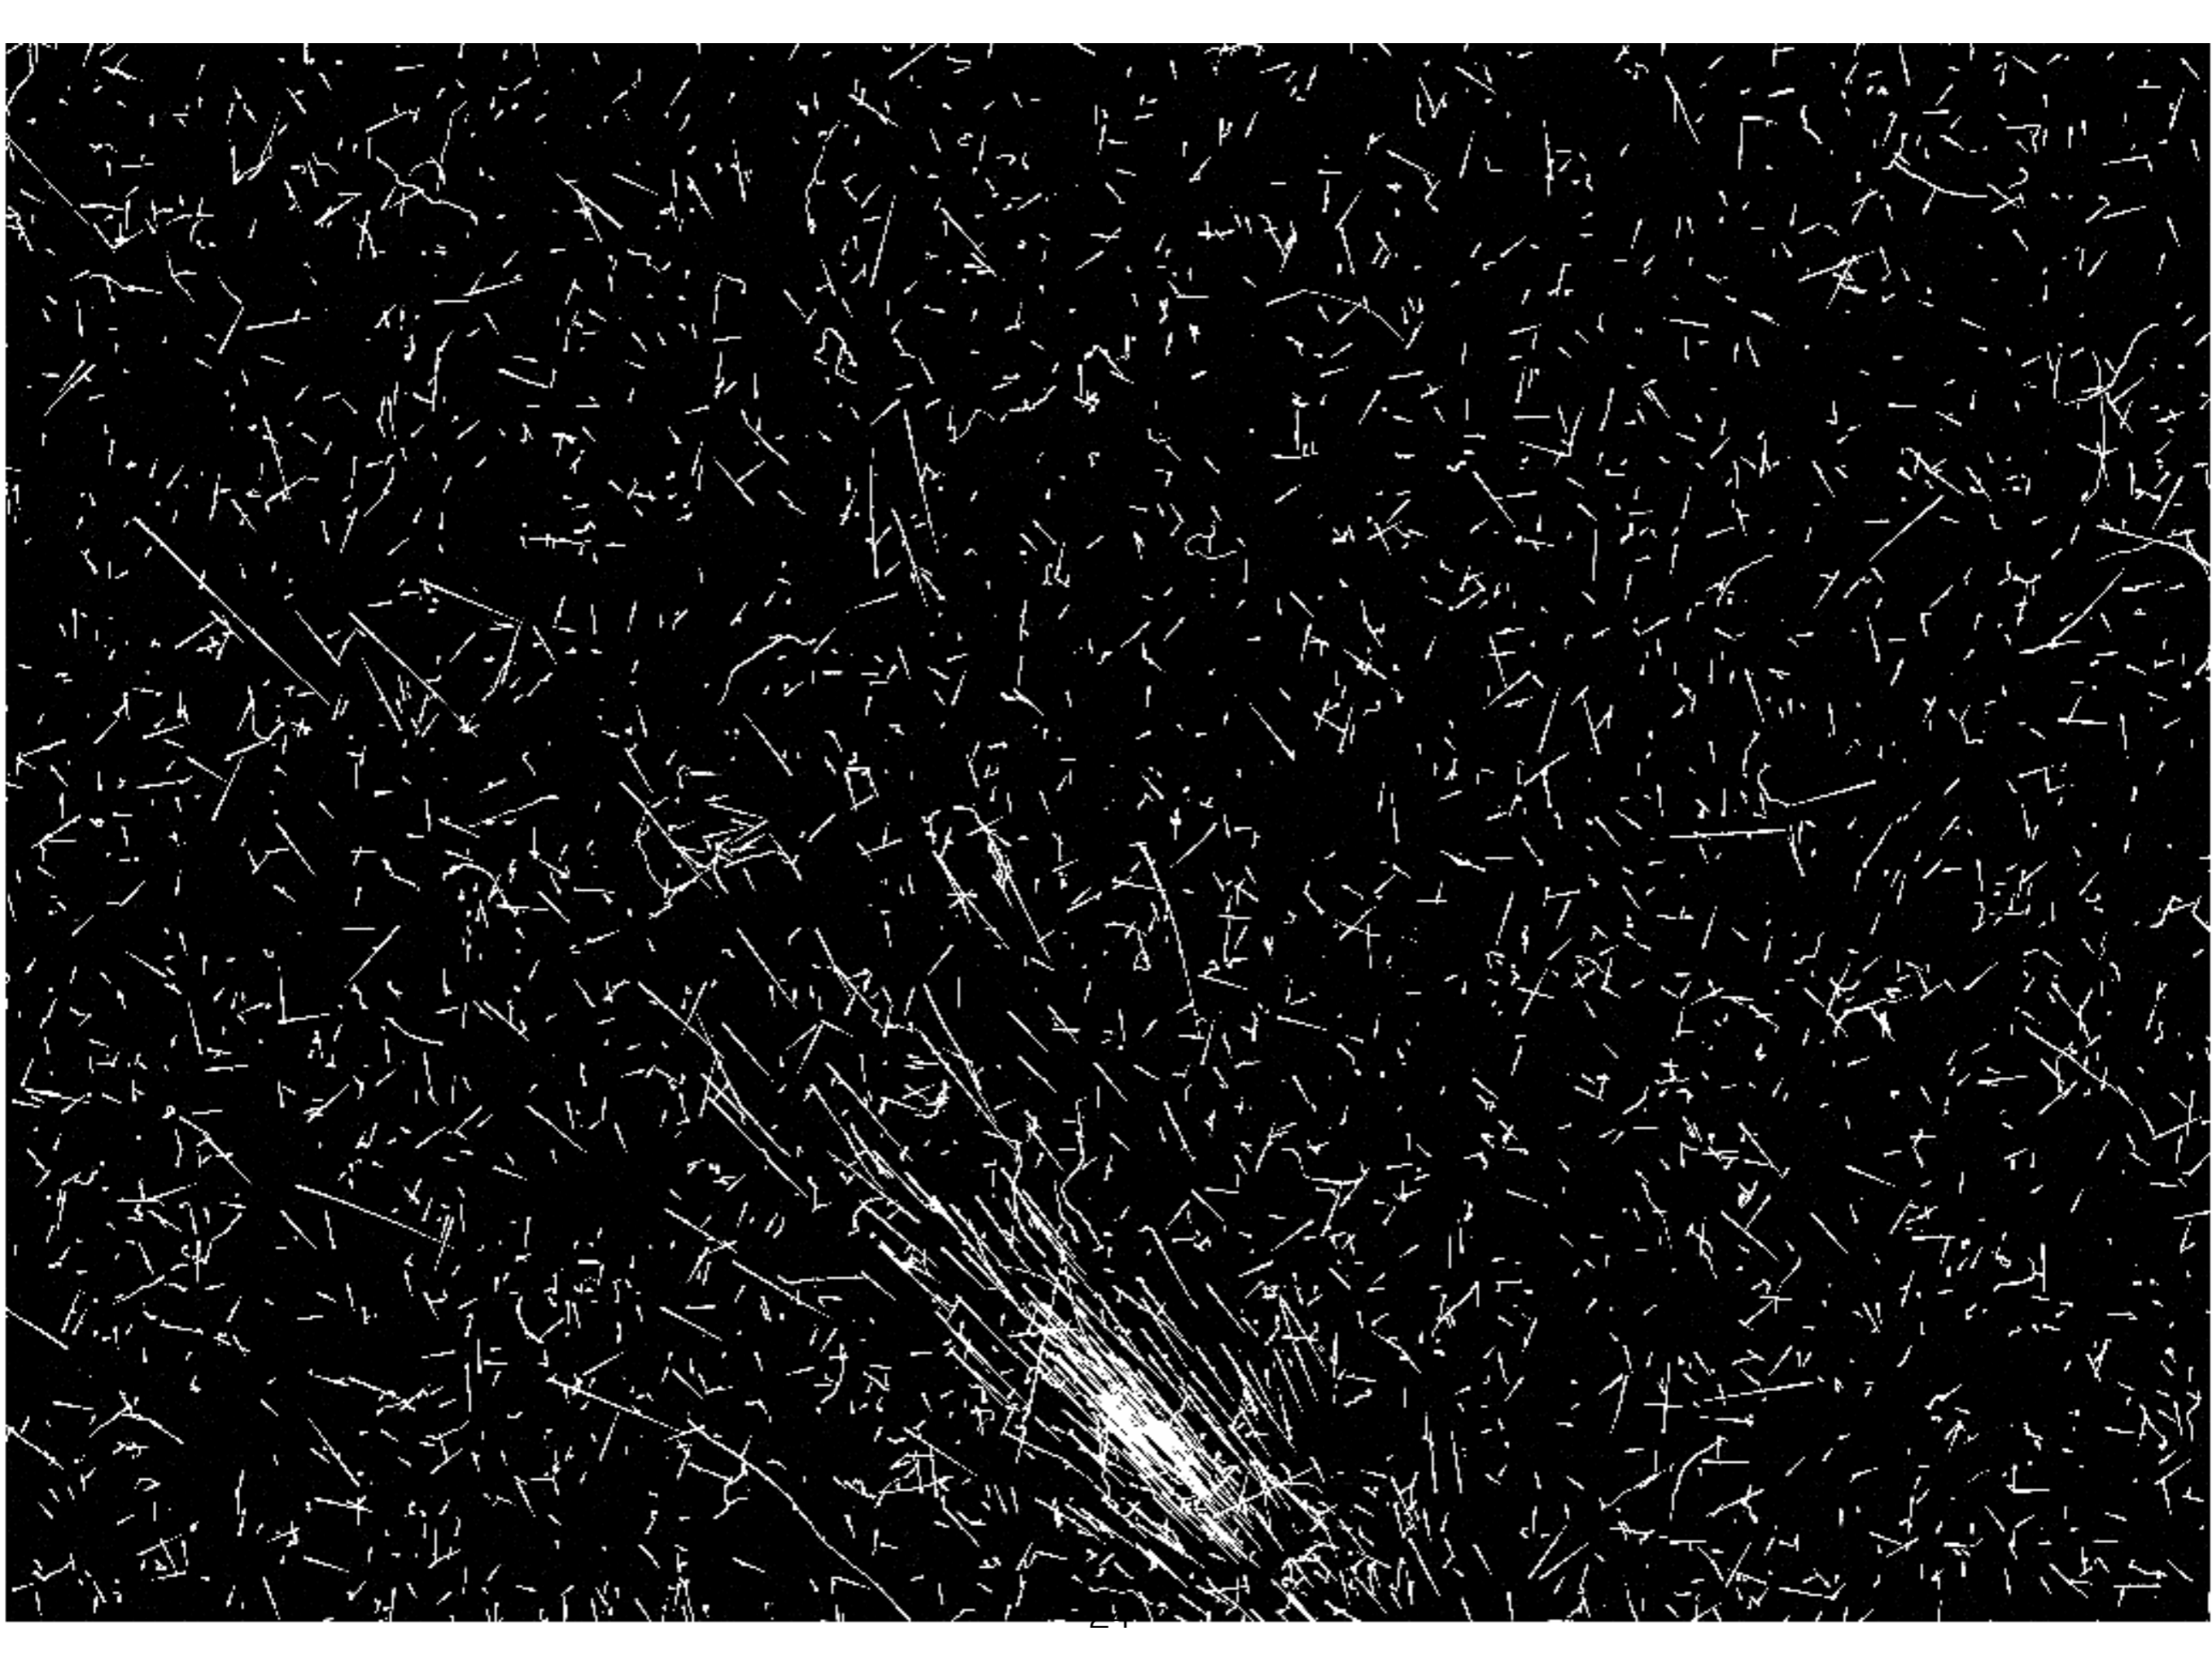

(we are not ready to show the results, but will try to share our excitement about this data)

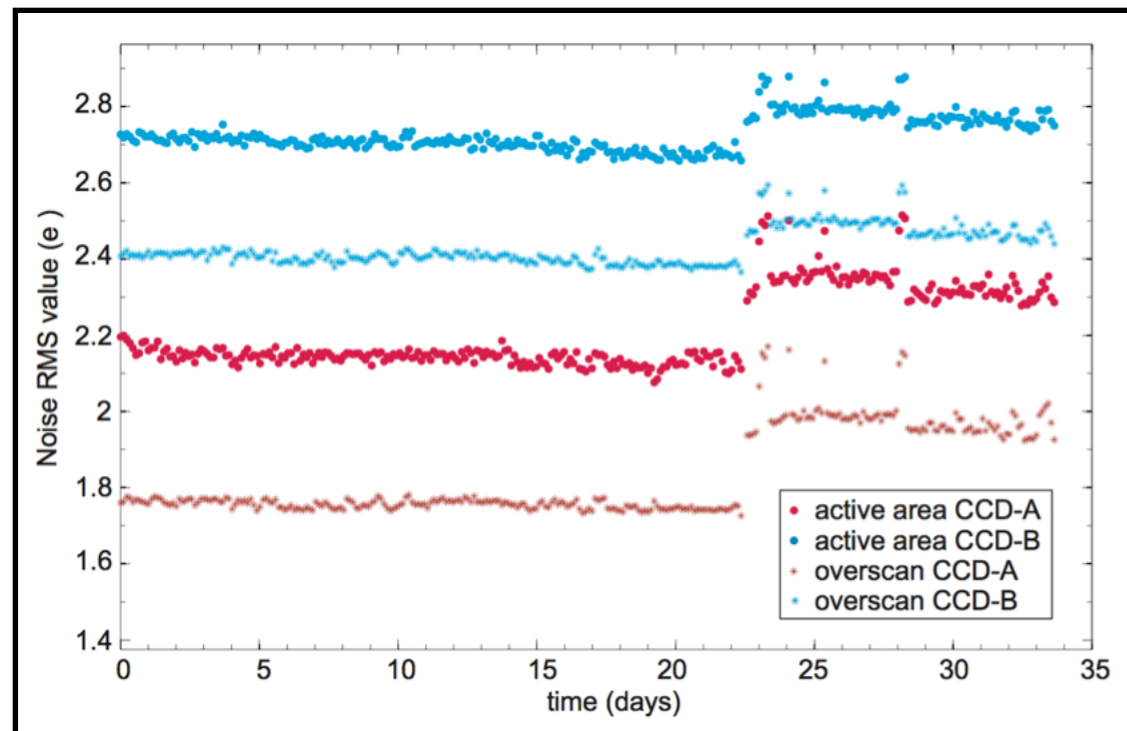

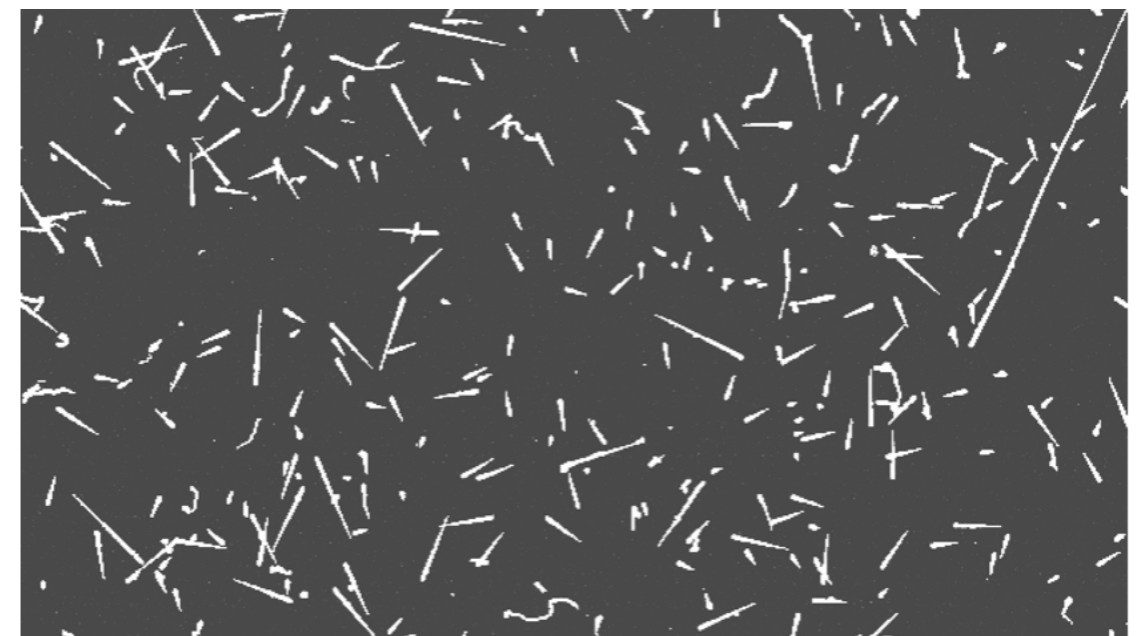

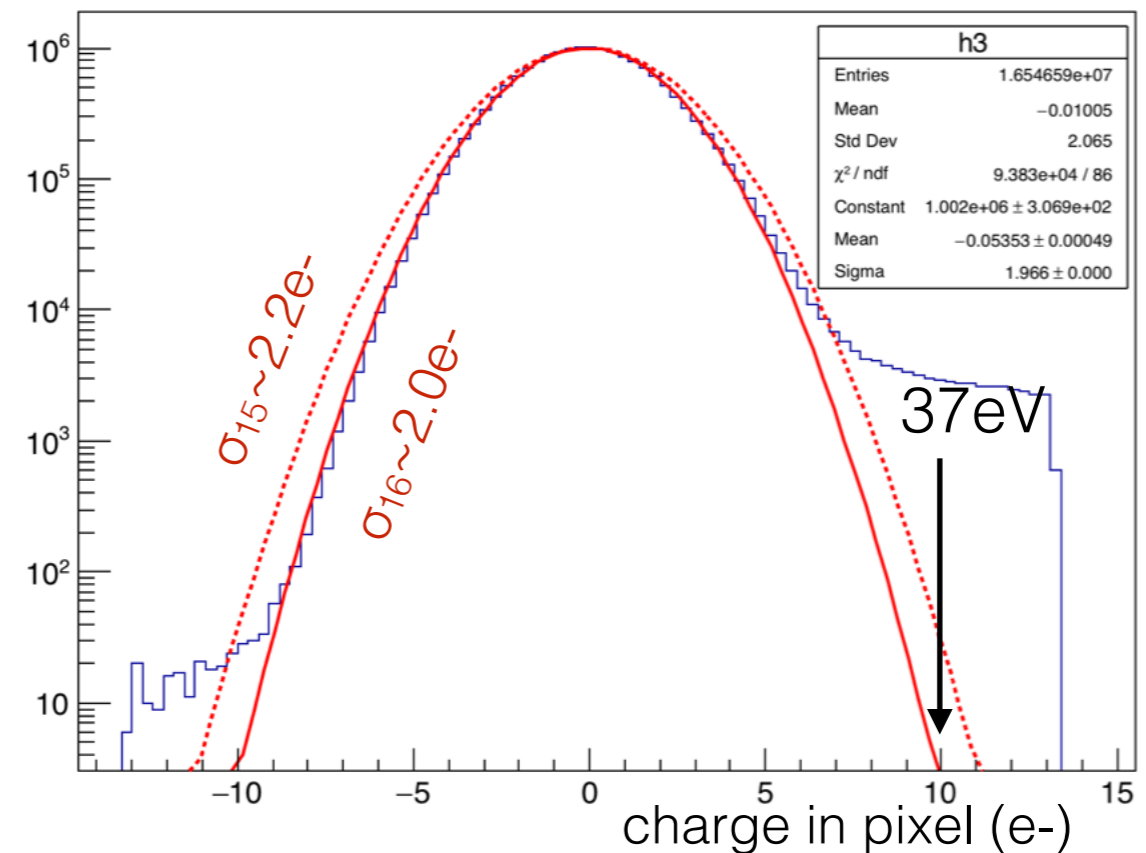

2015 engineering run

2015 we had a $2.2e^-$ noise in the best CCD for the active area of the detector. This means that we had dark current, or IR photons hitting the detectors.

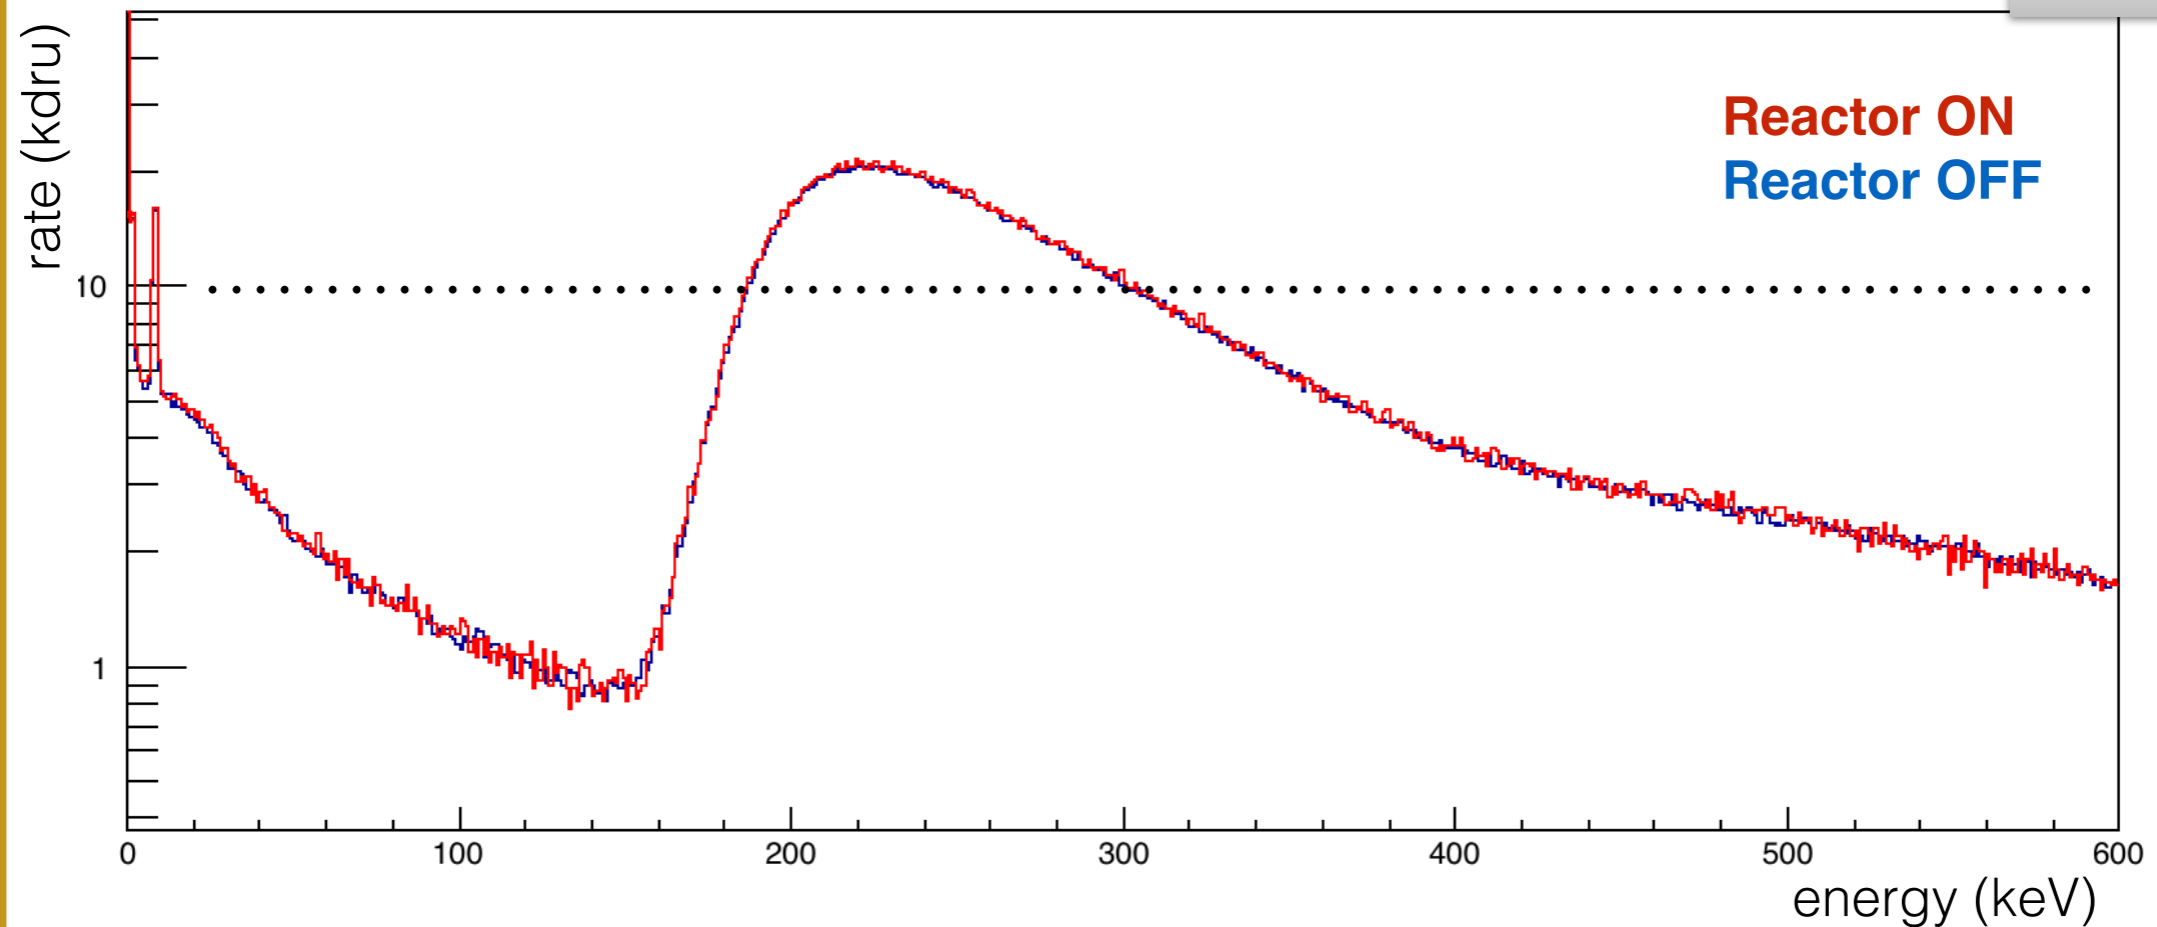

This 10% decrease in the noise is a big deal. It corresponds to ~ 10 increase in the rate of noise hits at ~ 35 eV.

2016 image example

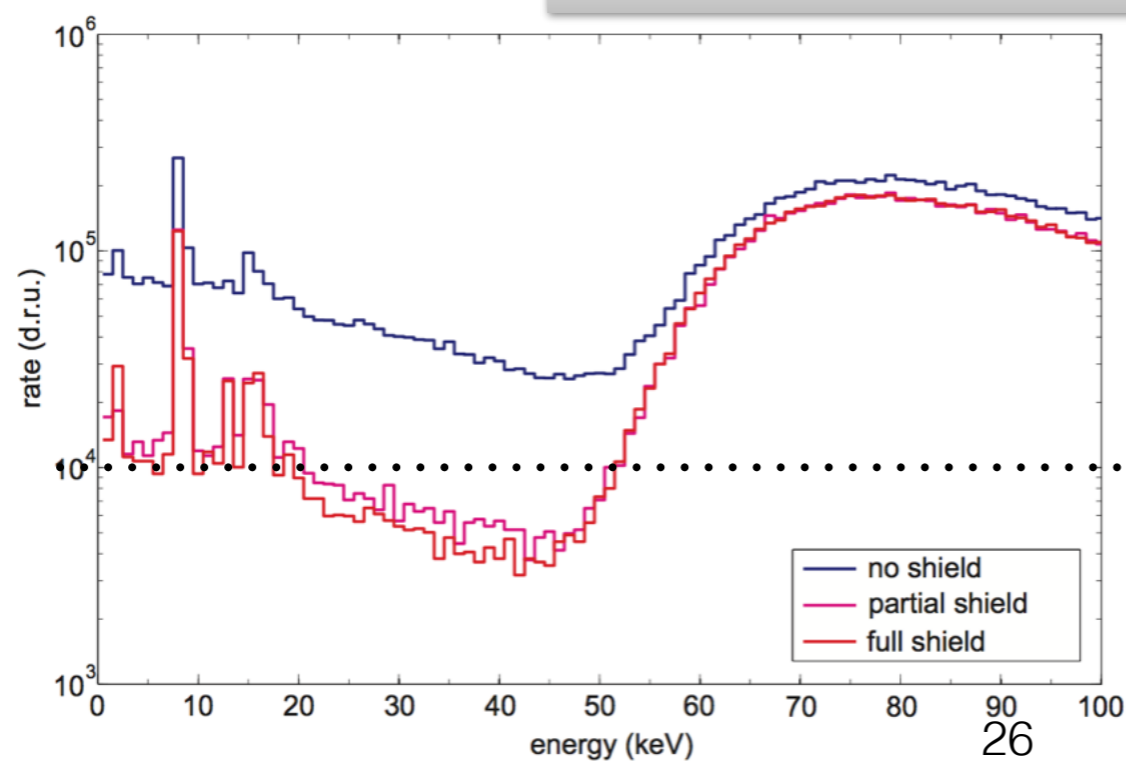

the histogram above also shows the hits from real tracks.

2016

2015 engineering run

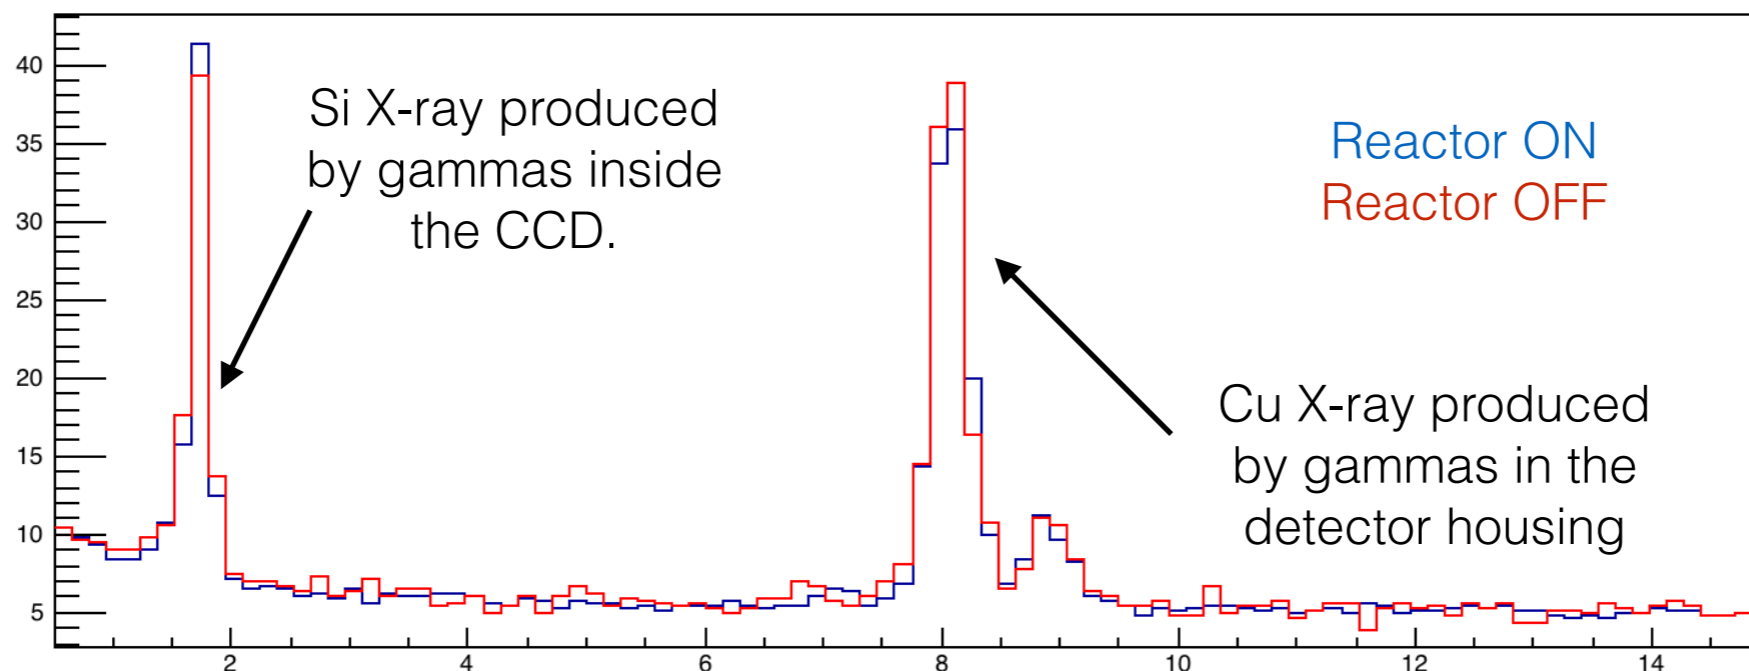

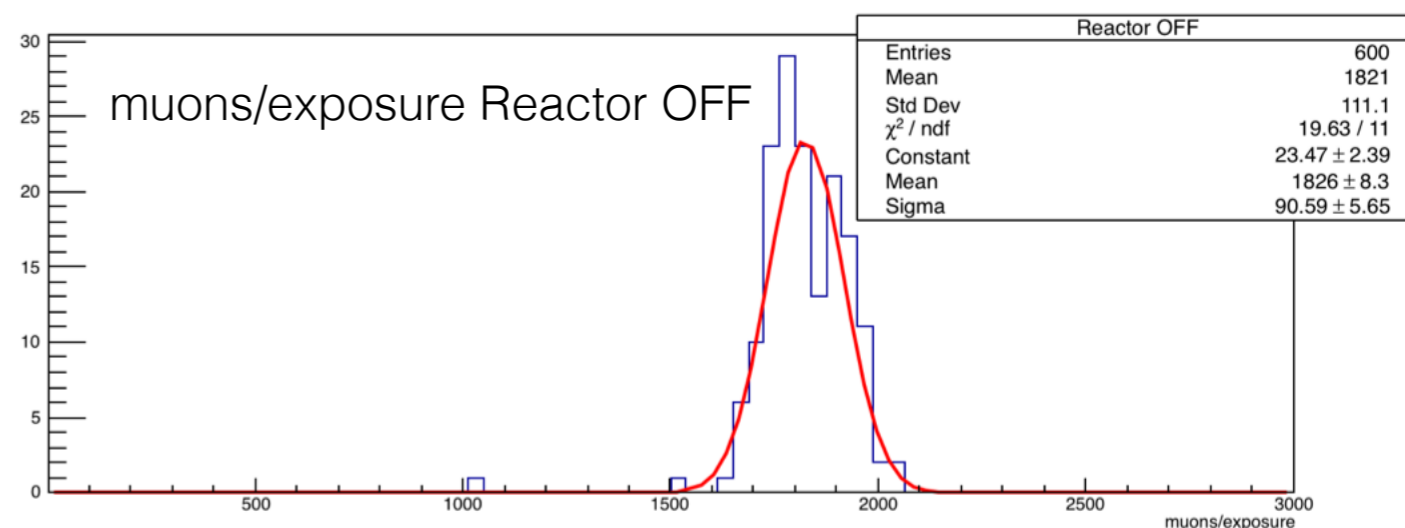

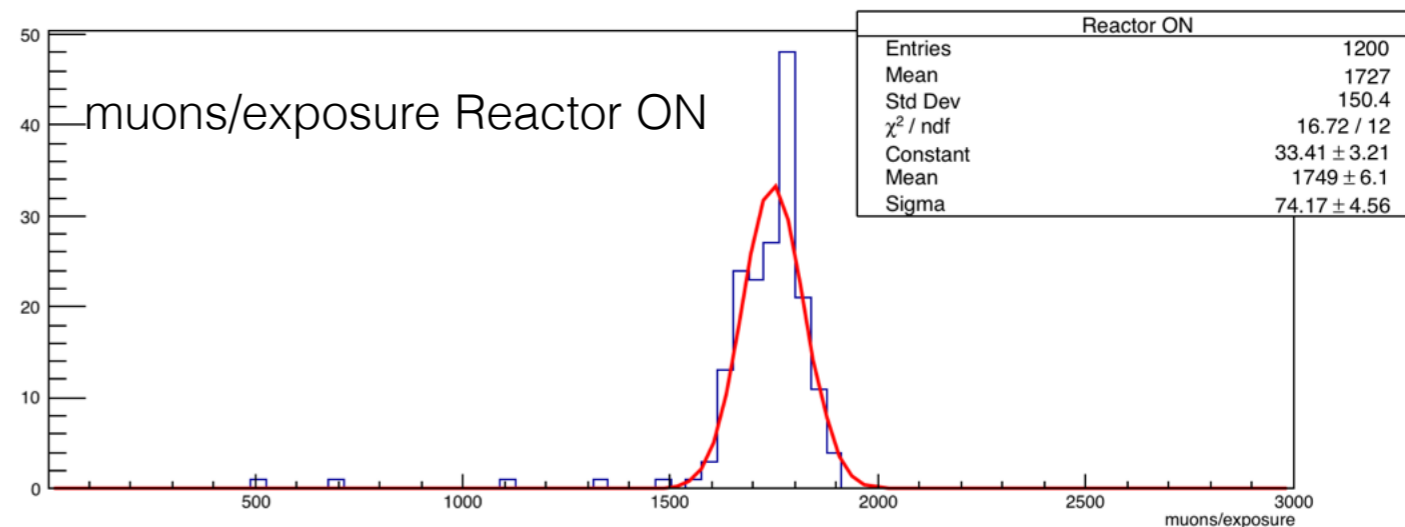

background improvement in the new configuration. We eliminated ceramic spacer (AlN) in the detector package. This eliminated all the ~ 15 keV lines produced by the U and Th decays. It also lowered the background significantly.

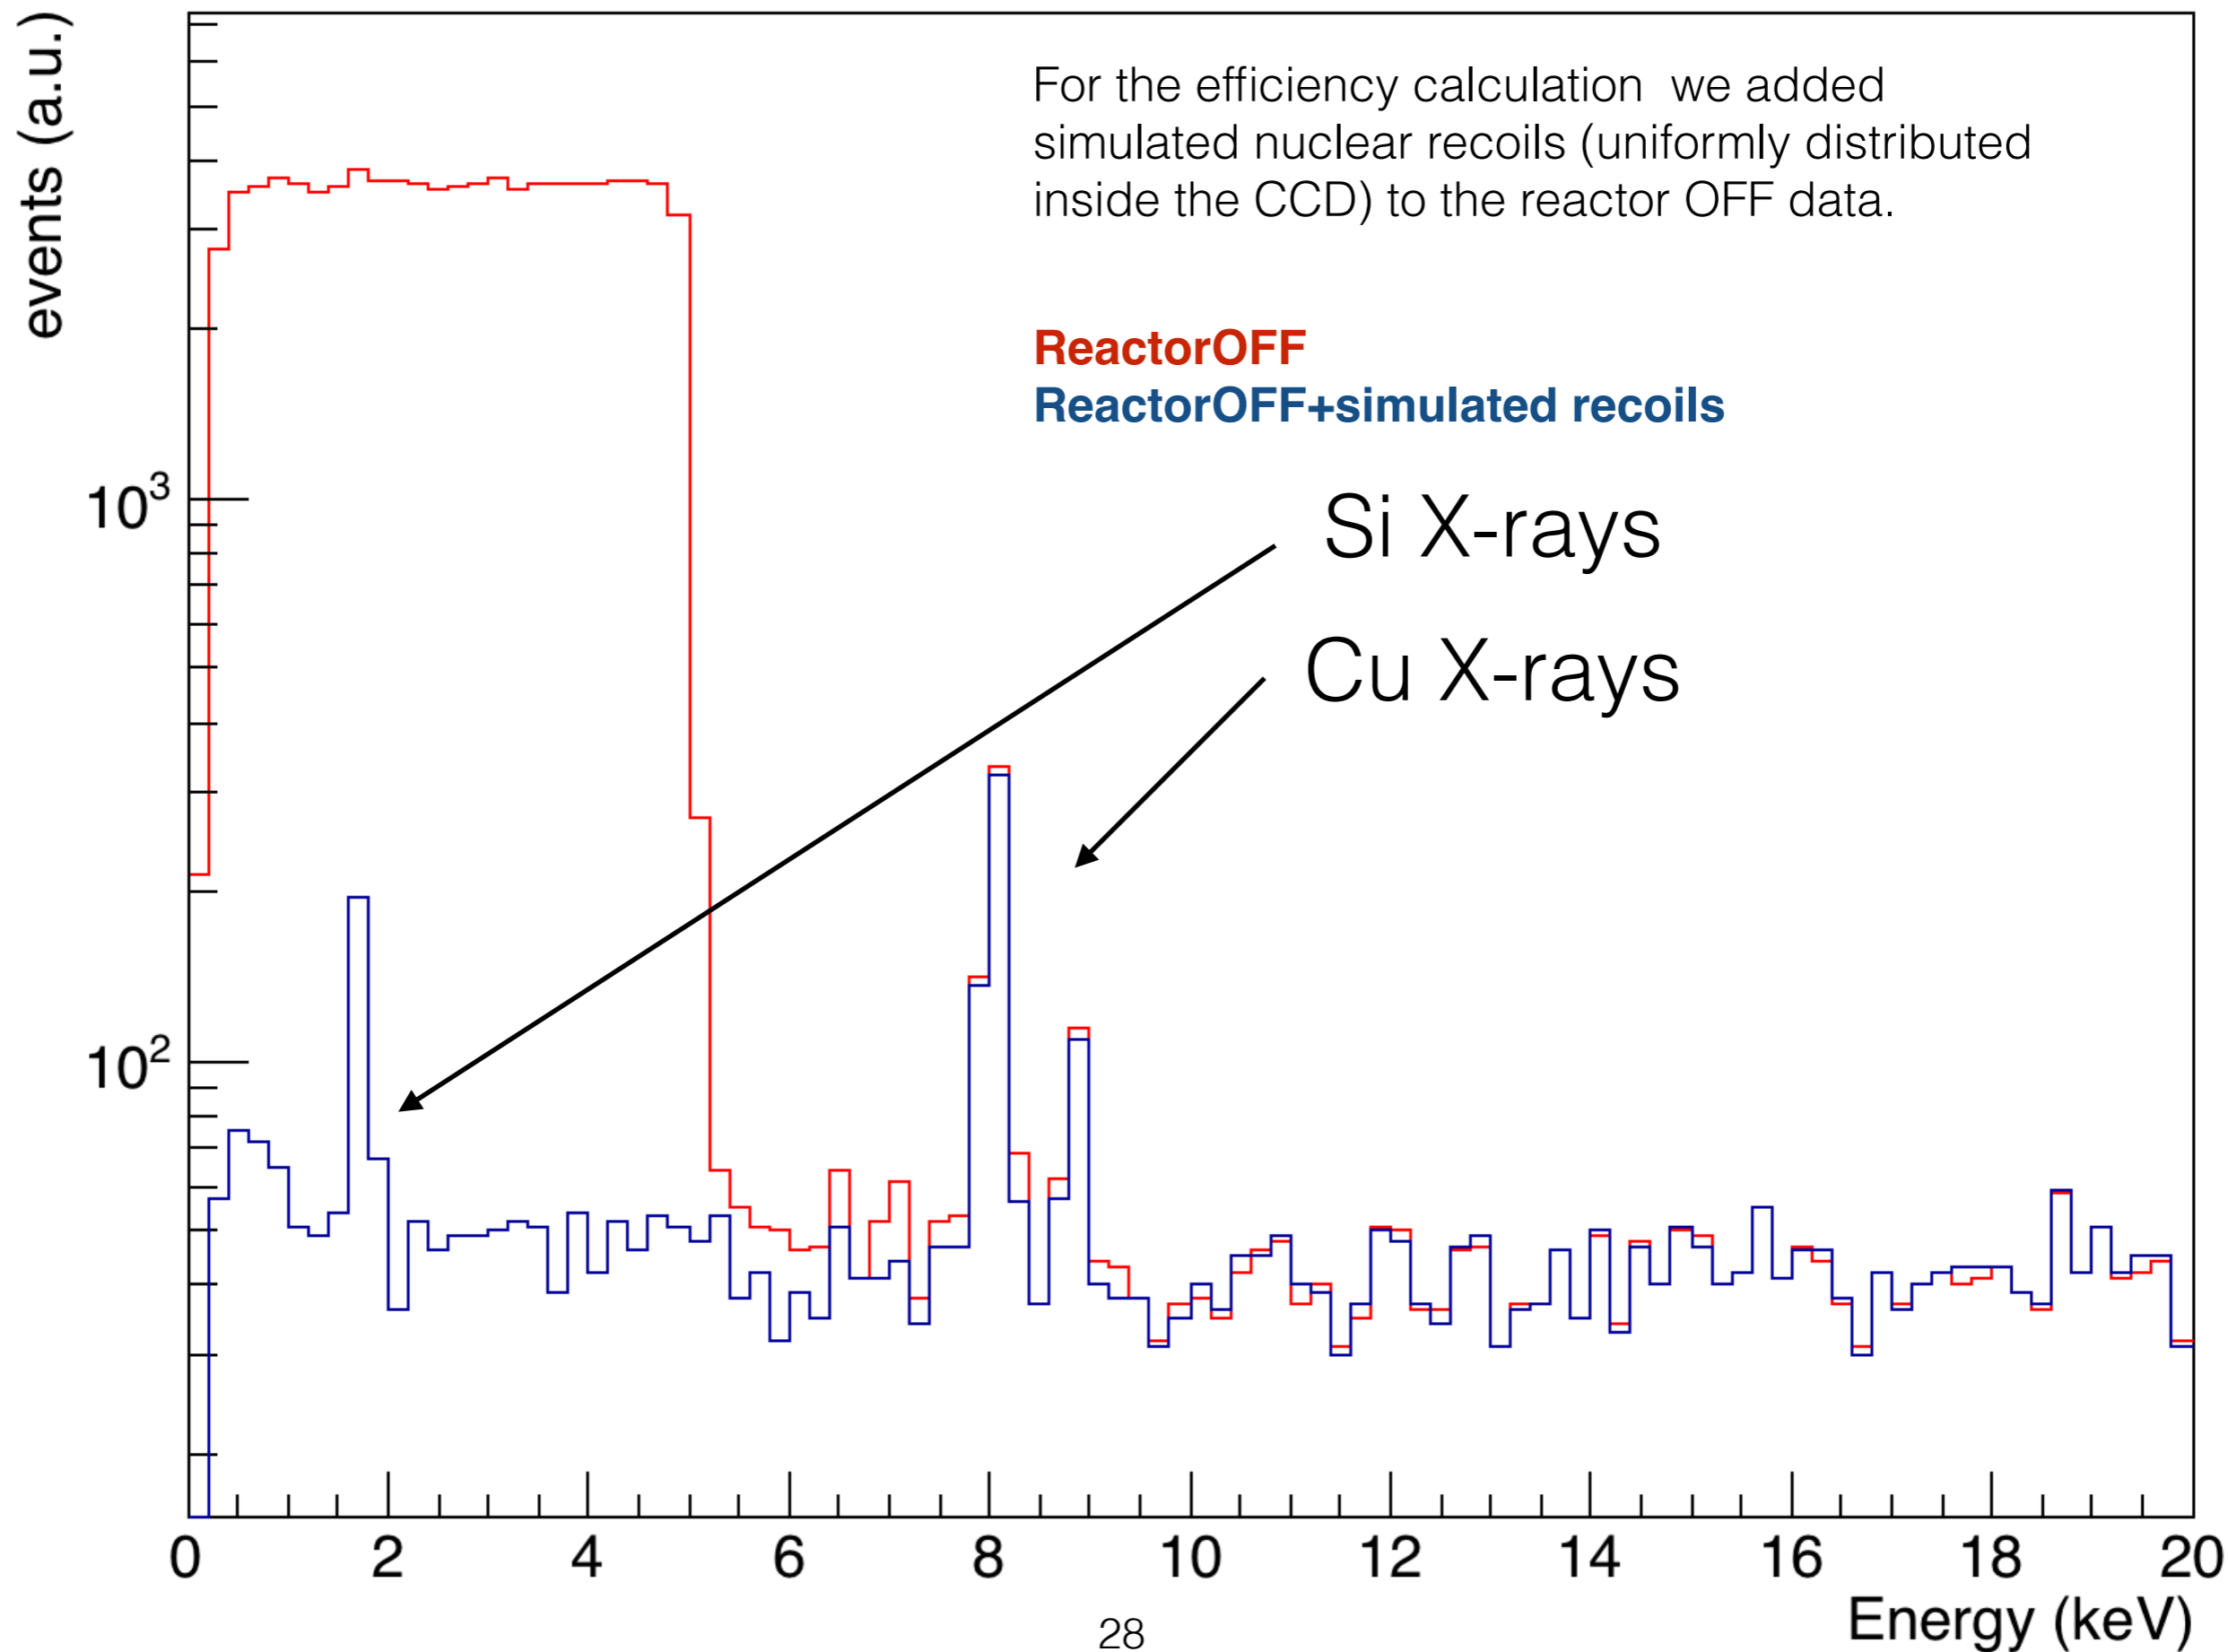

The bump from muon tracks is now at 250 keV because we went from 250 μm silicon to 675 μm .

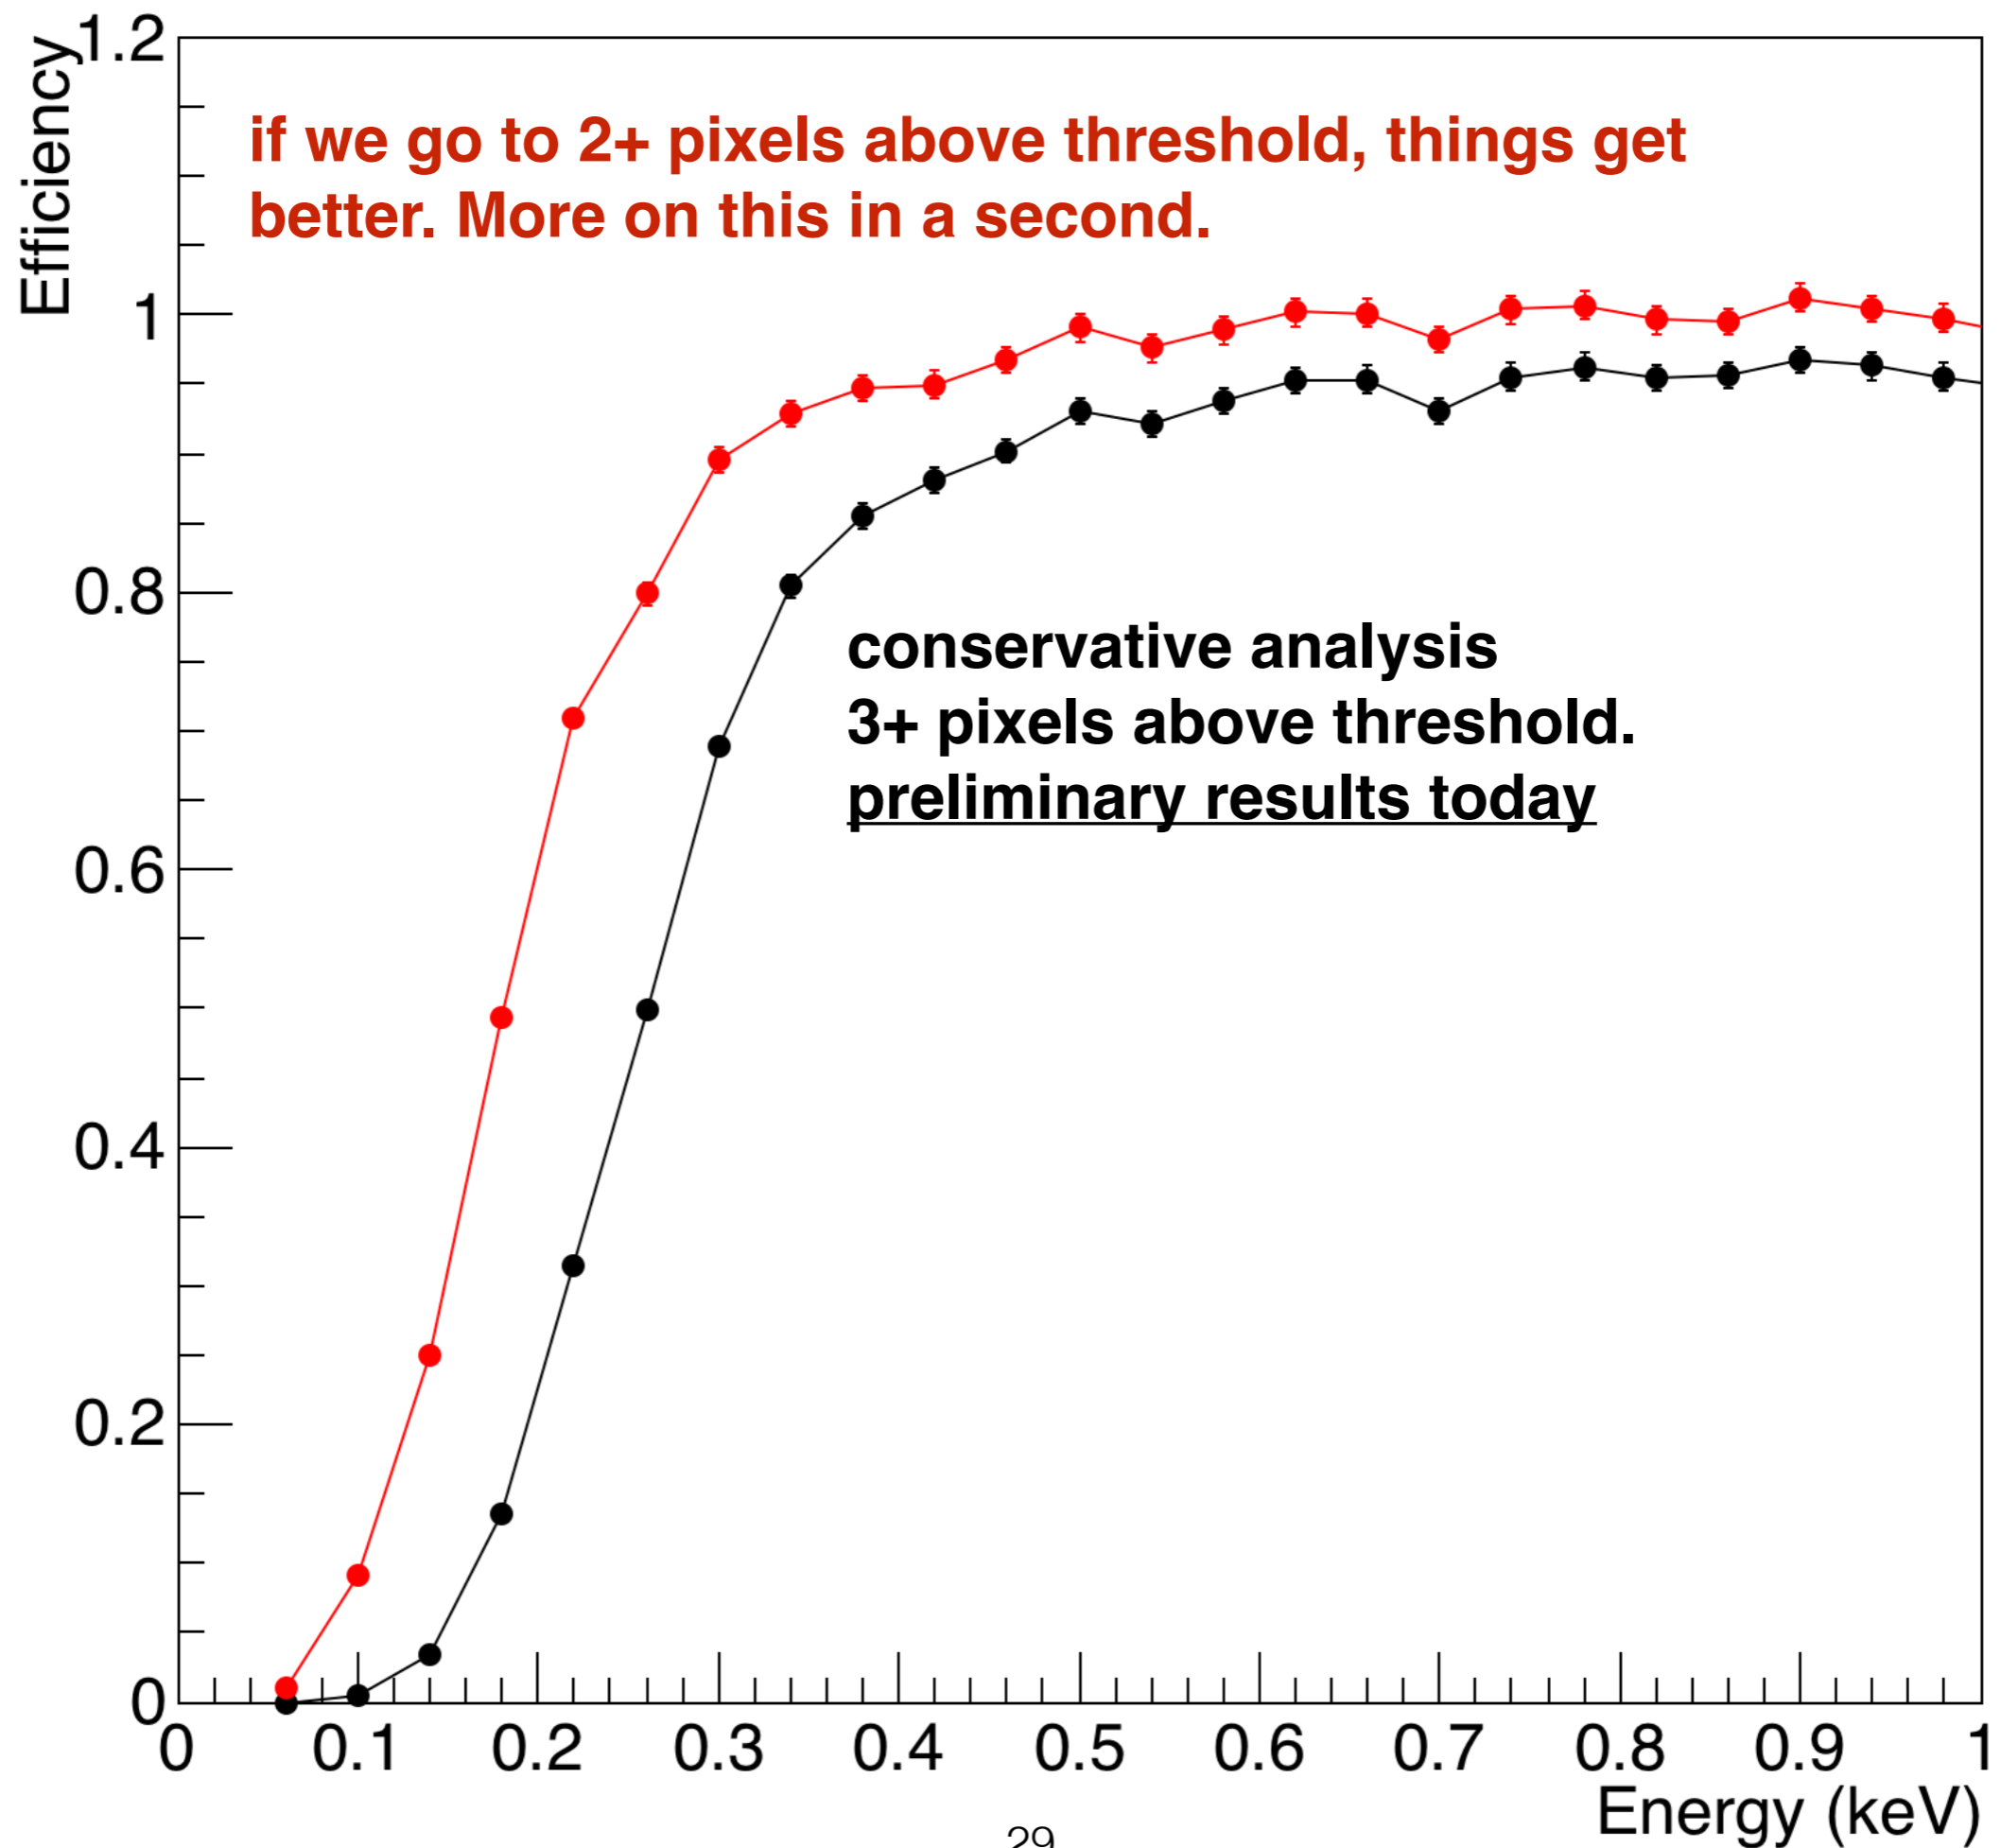

Comparing Reactor ON/ OFF backgrounds.

the muon flux is not the same, it is higher when the reactor is OFF. Makes sense due to weather.

fluorescence X-rays are the same reactor ON/OFF. This point to a stable gamma background.

2016-2017 data

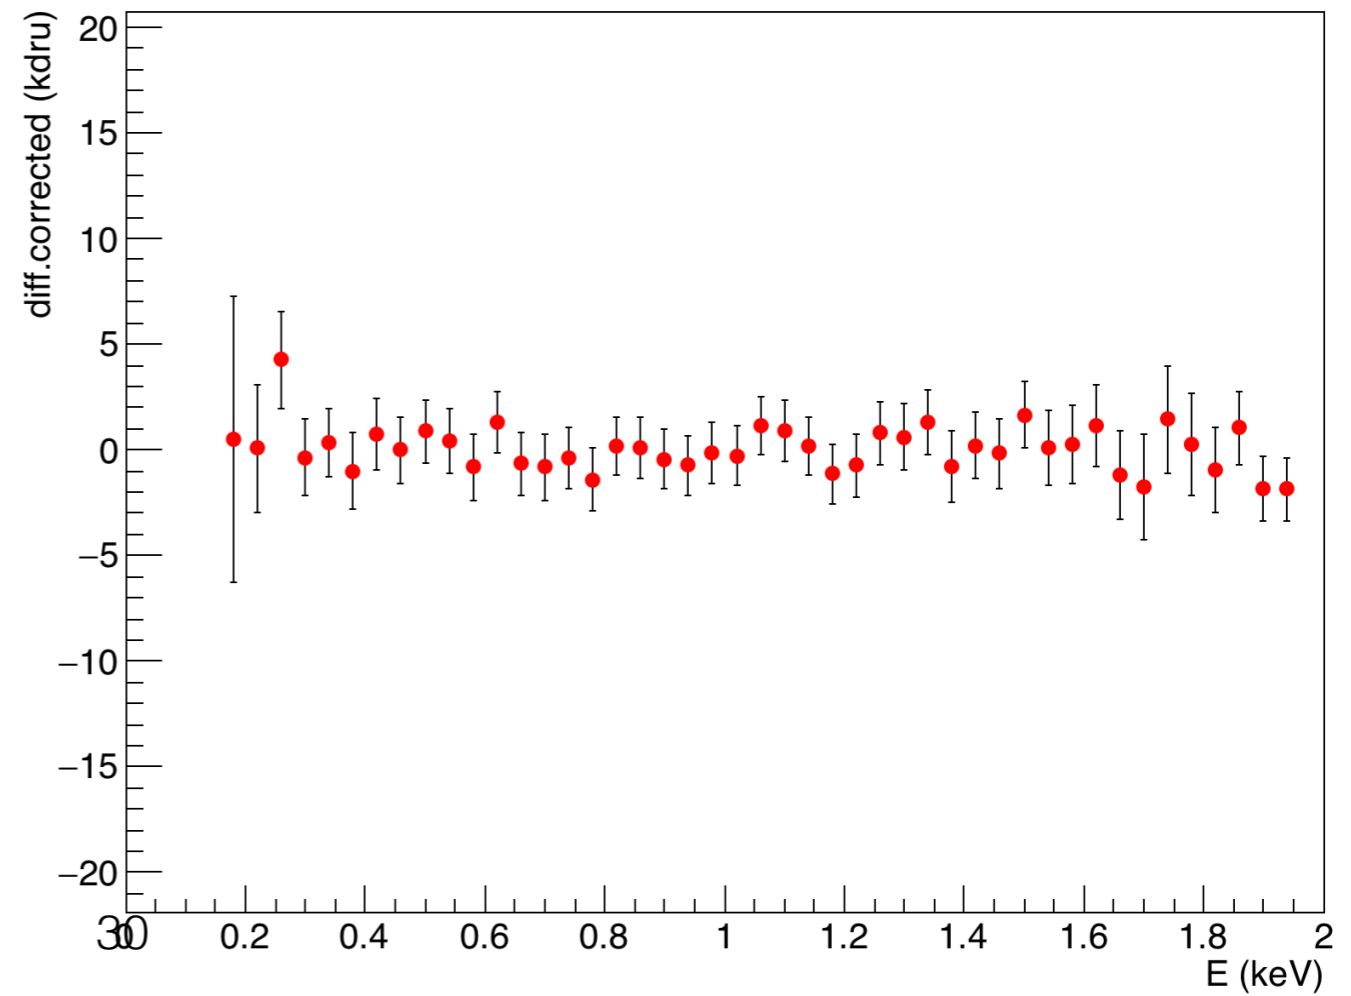

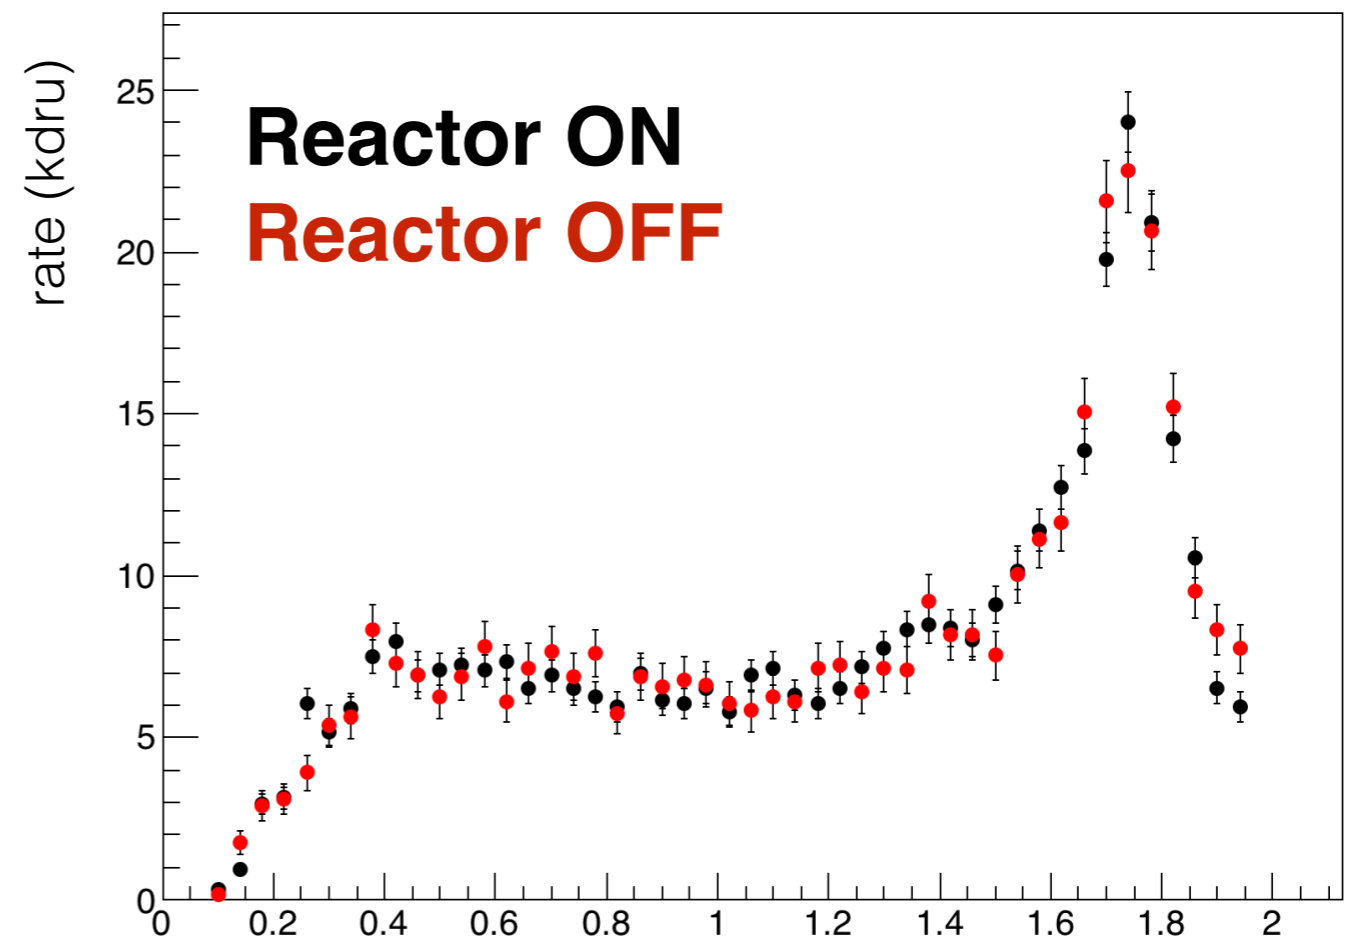

Preliminary

For this analysis we selected the detectors with less “cosmetic” defects.

Exposure RON = 704 g-day
Exposure ROFF = 339 g-day

2+ pixels above threshold

Data collected between
September 2016 and Feb2017.

Data collected between
September 2016 and Feb2017.

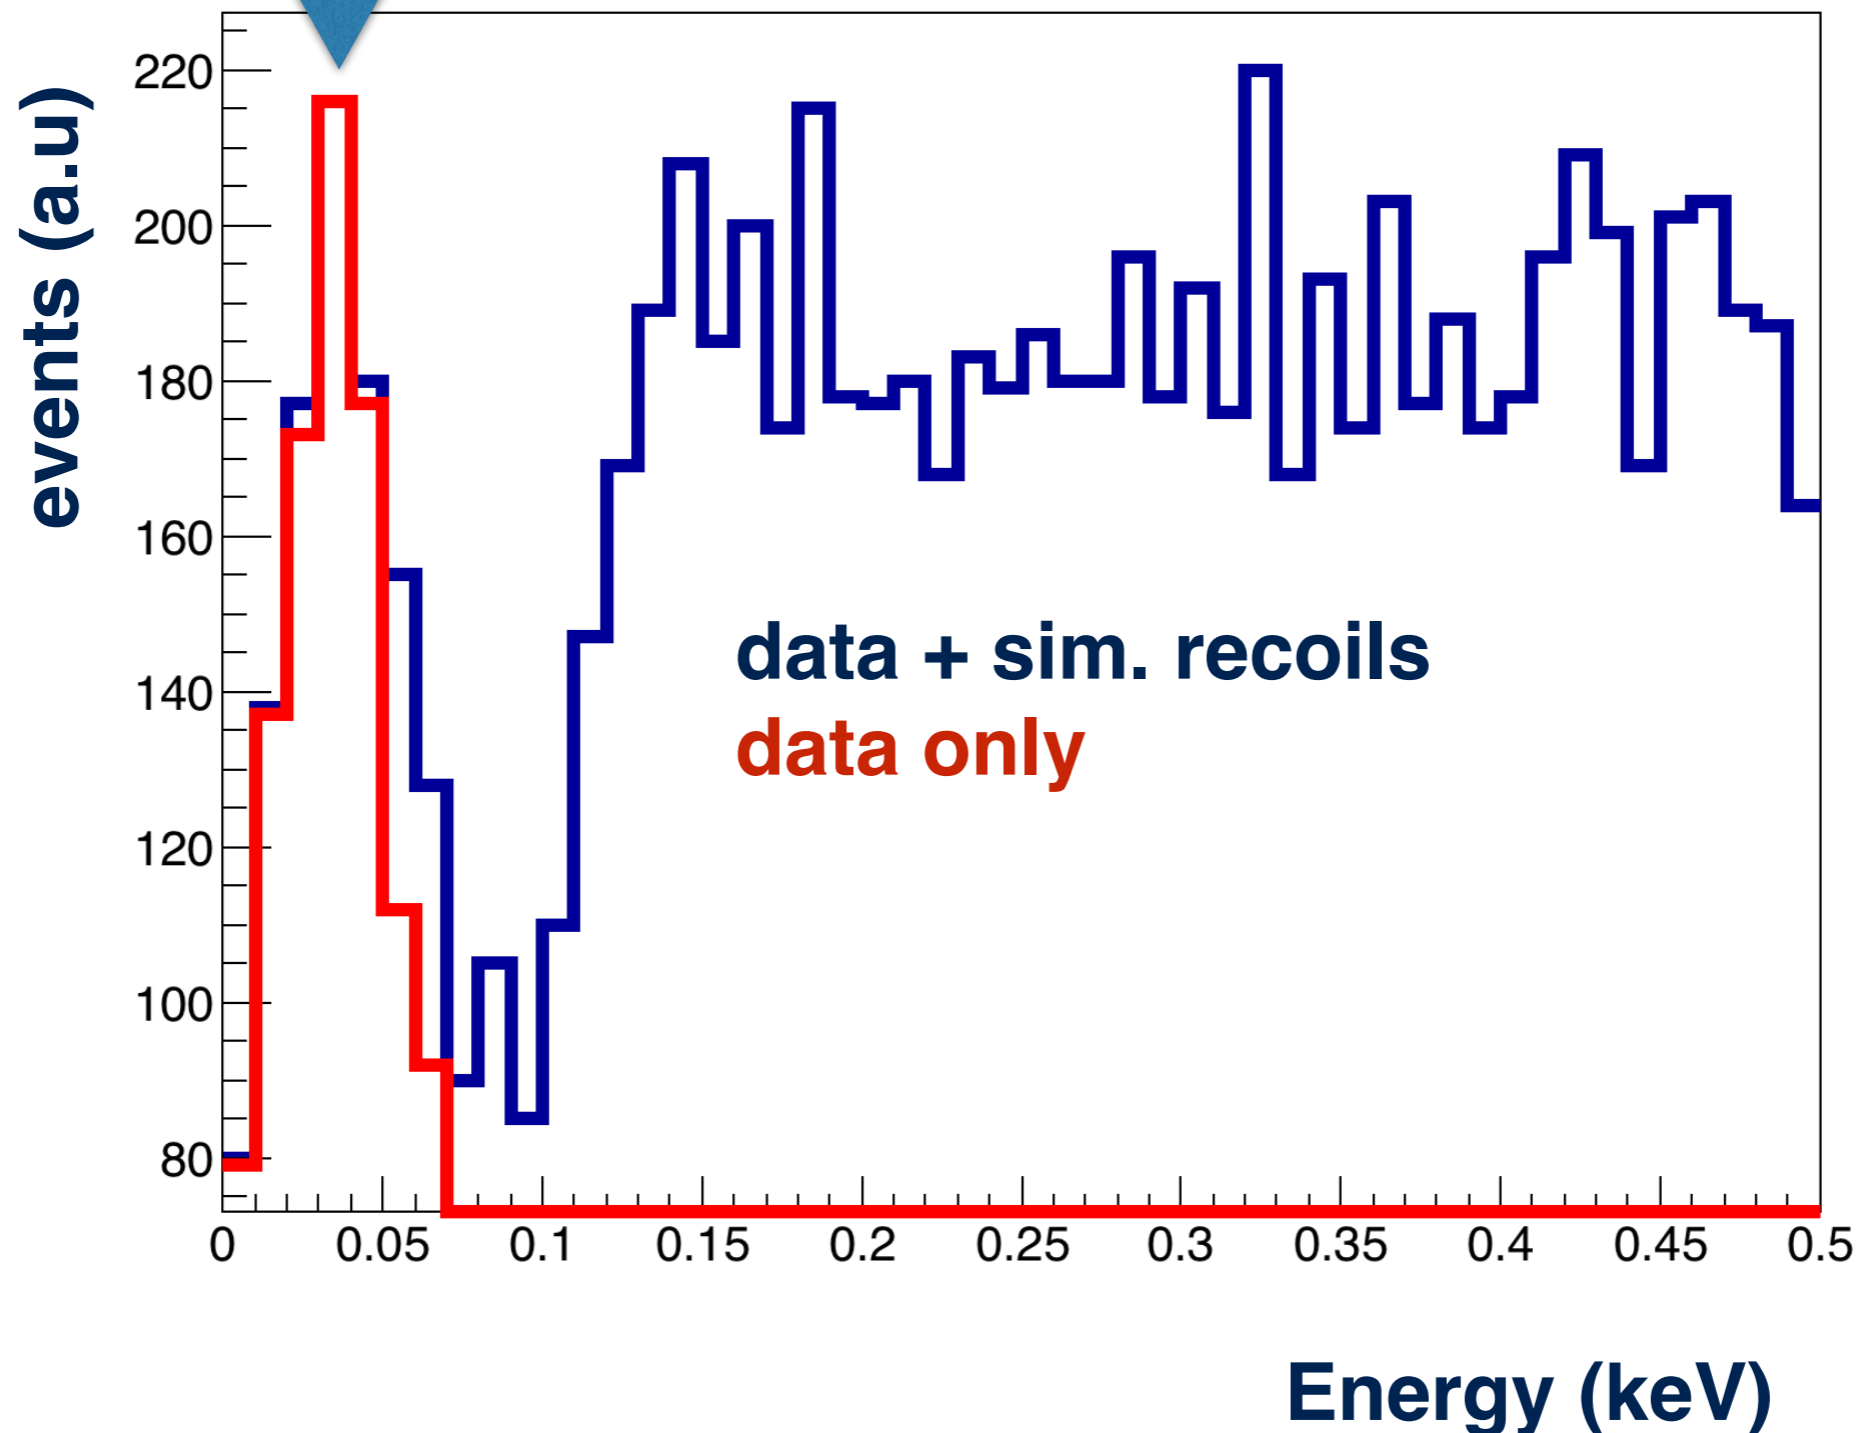

**big improvement over engineering
run 2015-2016**

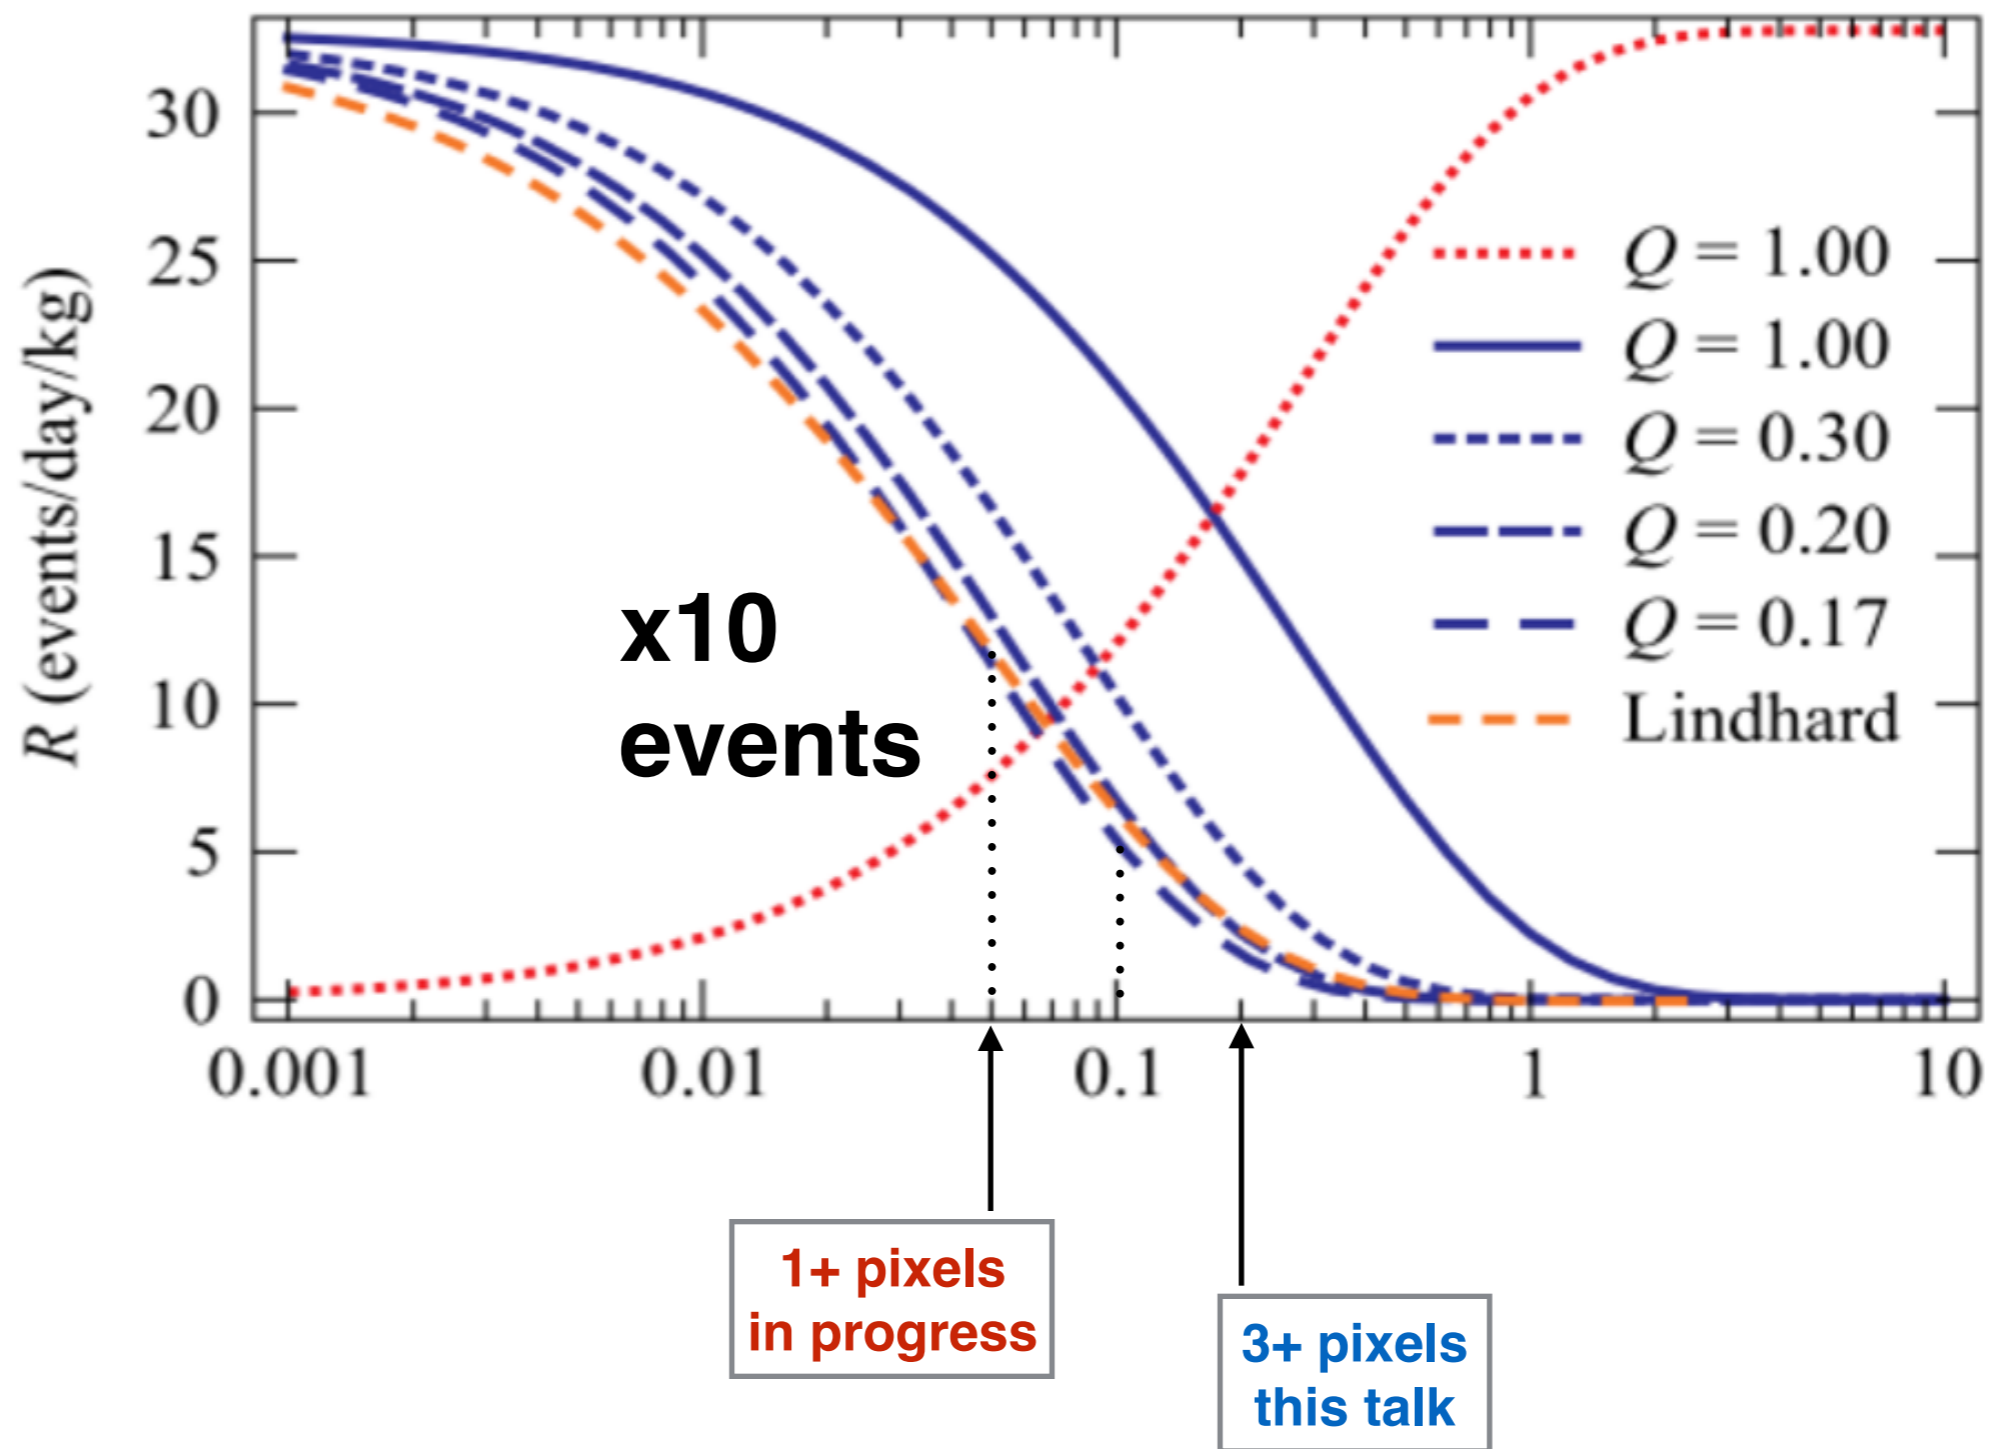

noise

This shows the detail of the low energy analysis with 1+ pixels above threshold. Using this events is our final.

2016-2017 data

Preliminary

For this analysis we selected the detectors with less “cosmetic” defects.

Exposure RON = 704 g-day
Exposure ROFF = 339 g-day

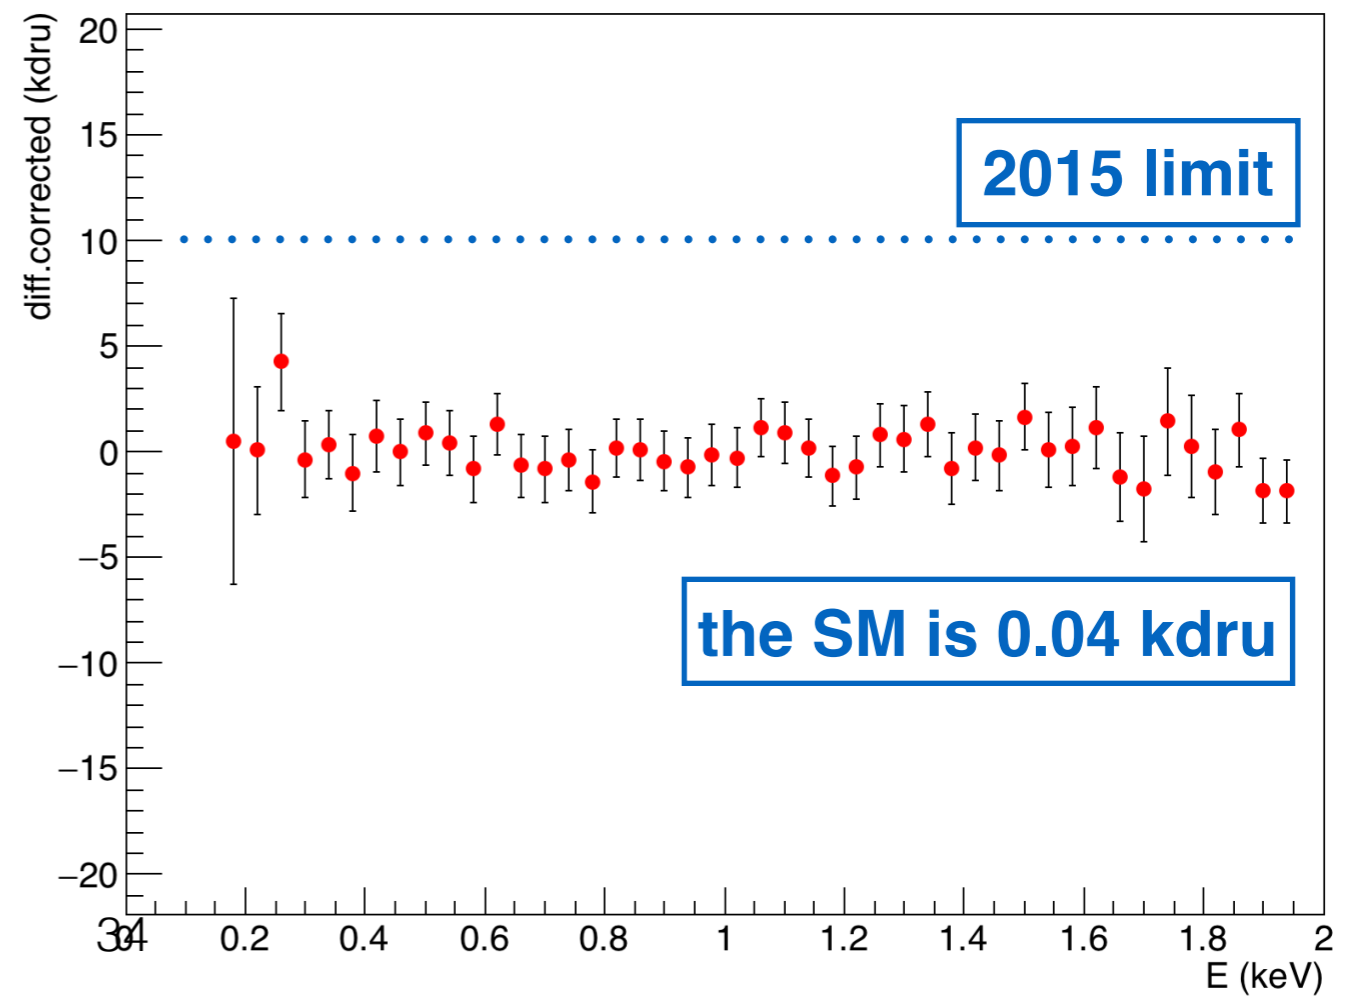

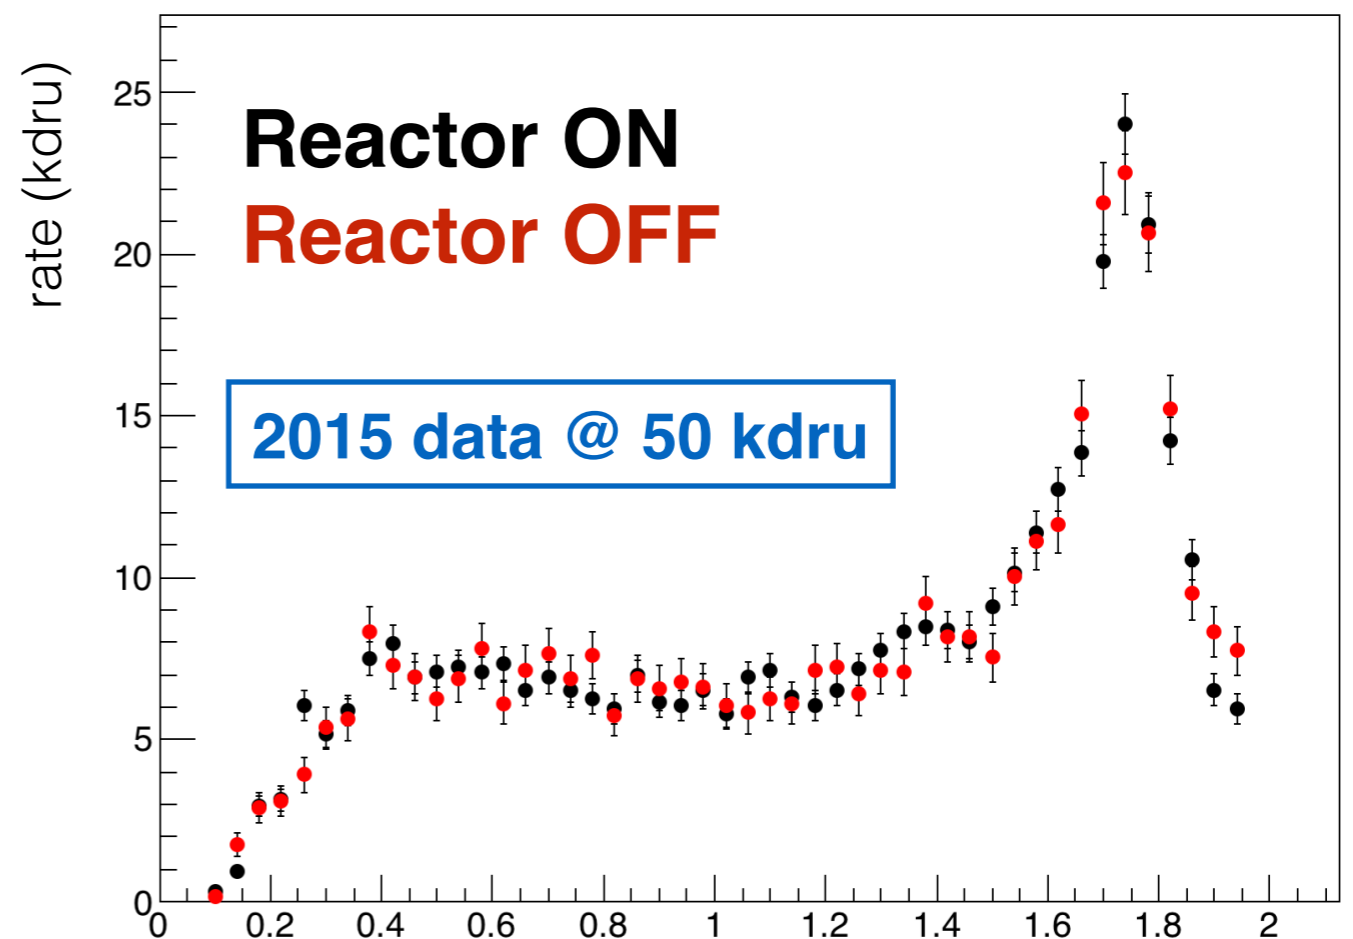

2+ pixels above threshold

Data collected between
September 2016 and Feb2017.

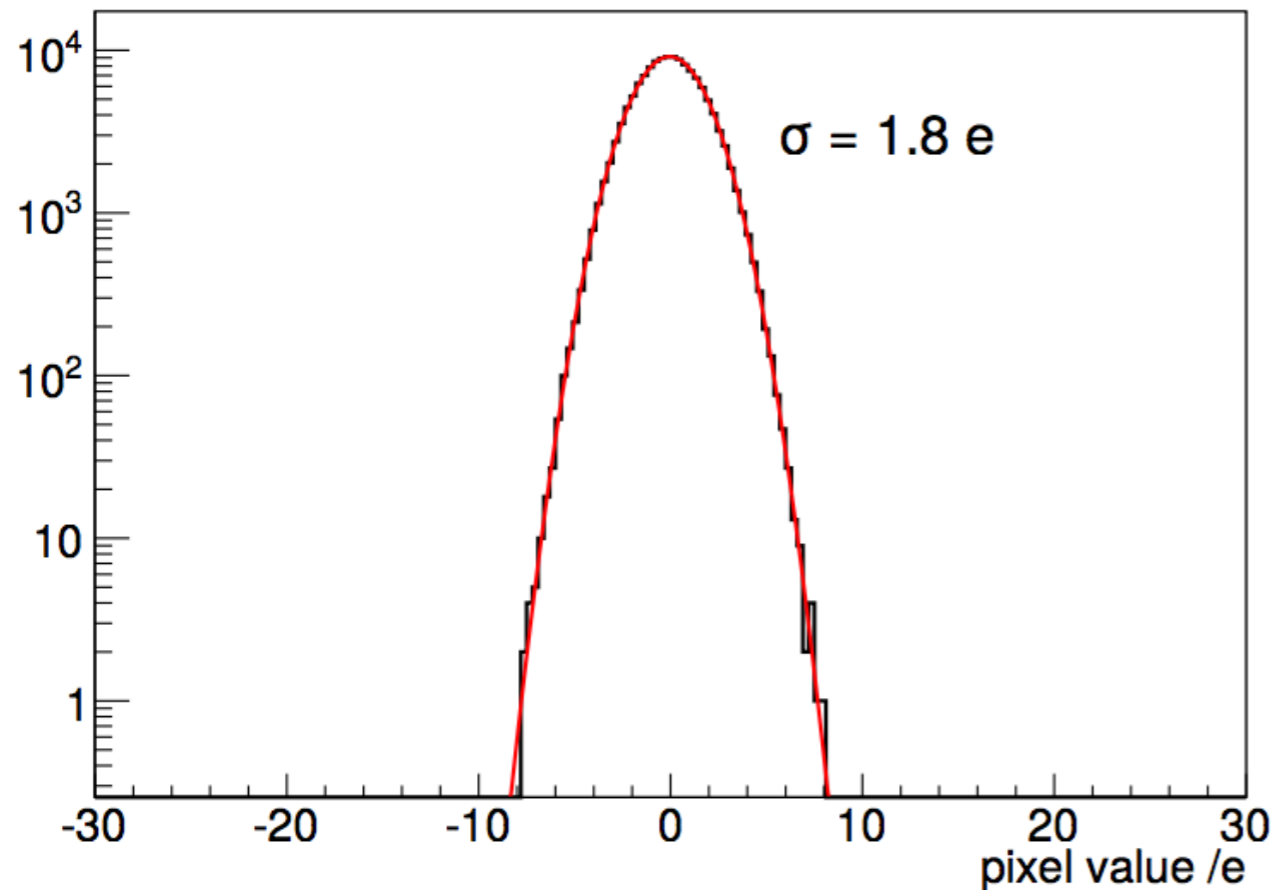

SM expectations : 0.04 kdru @ 0.22 keV
here uncertainty is 1.8 kdru @ 0.22 keV bin

using 1+ pixels above threshold, efficiency starts at ~60eV, SM signal goes up by ~10.

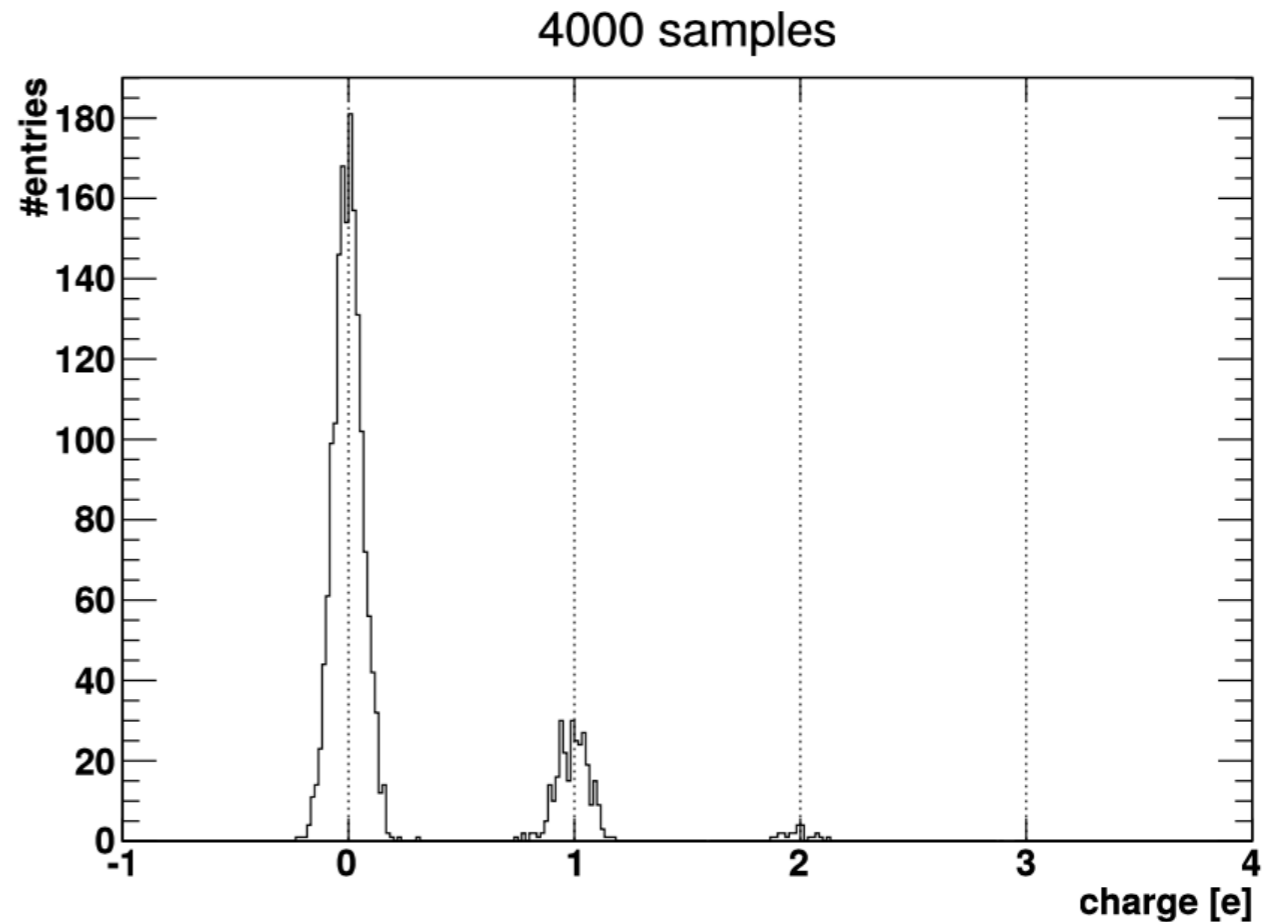

We plan to have 3 times the data after the shutdown in early 2019. SM within reach!

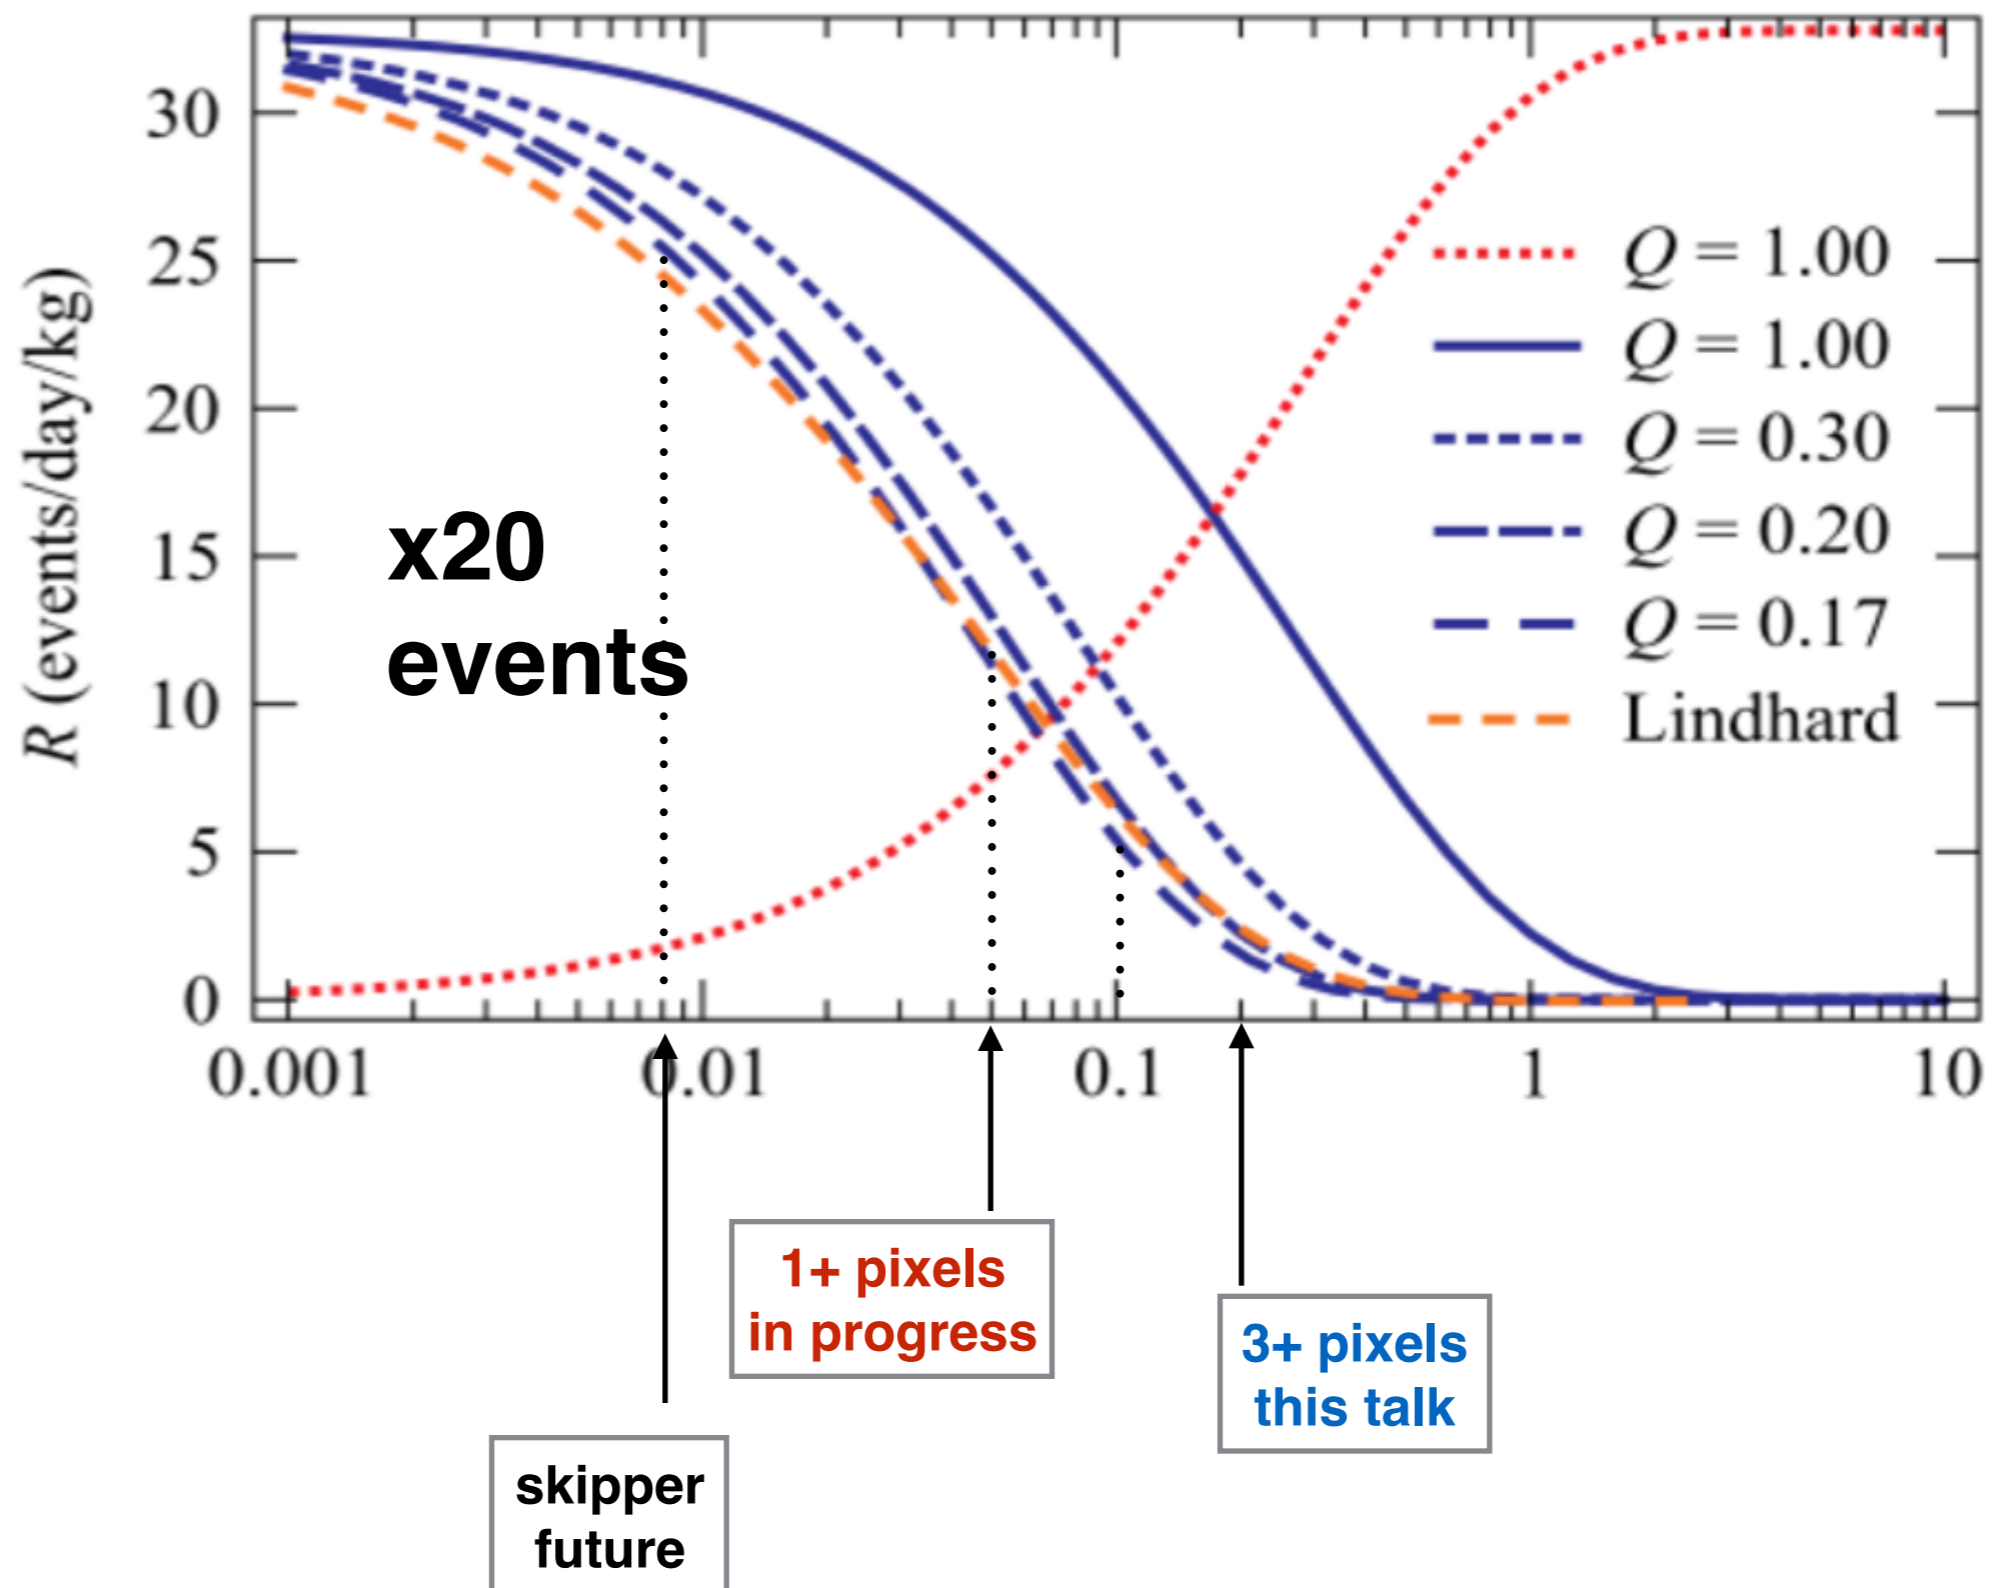

CONNIE now

skipper CCD

New CCD technology demonstrated this summer by Javier Tiffenberg et al (arXiv: 1706.00028) allows reduction of the threshold by another factor of 2. The plan is to install a couple of these detectors in CONNIE also. Will need a new ionization efficiency measurement.

Conclusion

- Preliminary analysis of high energy events (200 eV) show tremendous improvement over engineering run.
- Current plan is to run for around two more reactor shutdowns with higher operations efficiency to reach SM.
- Longer term, we are considering lowering the threshold a factor of 10 with the demonstrated Skipper CCD.
- Looking forward to join COHERENT in the fun!
