Diverse Types of Slums in Bangalore: Studying Policy-Relevant Differences

Anirudh Krishna, Duke University
in association with Grady Lenkin, Neelanjana Gupta, Erik Wibbels, MS Sriram, and Purnima Prakash

Abstract
Combining a study of satellite images with on-the-ground neighborhood surveys helped identify four separate types (and many subtypes) of slums in Bangalore. Detailed interviews with more than 2,000 households in a sample of two types of slums – the best and the worst – helped confirm that there are clear differences across types. Migration patterns, length of residence in Bangalore, living conditions, asset holdings, investments in education and health care, and prospects for the future vary widely. Higher and lower degrees of informality are associated with different slum types. All types of slums are poorly served by the kinds of institutions that help make Bangalore a source of economic dynamism for others, but the extent of institutional disconnect is greatest for the worst type of slum. Connecting slum settlements with more robust institutions is an essential aspect of long-term policy formulation. More fine-grained policies recognizing the diversity of slum types will more effectively help improve the prospects for slum residents.
Gaining ground rapidly as the loci of the greatest economic dynamism in this era of globalization, large cities in the developing world are also becoming the centers of large inequalities in occupations, lifestyles, and housing conditions (Florida 2008; Moretti 2012; Porter 2000; Sassen 2001). “Nowhere is inequality more in your face than in India,” an article in the New York Times of December 19, 2013 notes. Beside luxury-brand stores and glass-walled office towers, no more than a couple of hundred yards away, there are people living in squalid settlements and close-packed slums.

Despite their rapid growth, extant knowledge about slums – about processes of settlement; trajectories over time; and social, political and economic dynamics – remains rudimentary. Planners in India distinguish between declared and undeclared (or notified, recognized, and unrecognized) slums, but events have overtaken these gross distinctions, resulting in the emergence of five and perhaps six distinct types of slums. How slum settlements differ at a point of time is poorly understood. How their trajectories over time vary is almost completely unknown. Such gaps in knowledge result in growing urban decay, segmented housing markets, proliferating squalor, corruption and wasteful expenditure, and rising inequalities in service provision.

Whereas scholarship was previously focused mostly upon poverty in rural area, recent investigations have been restoring the balance by looking at the conditions of poverty in urban slums. For the first time, in 2011, the Census of India presented separate estimates of the population in slums.1 Recent reports from other official agencies have also added much-needed knowledge about slums and slum dwellers.2 Considerable gaps in knowledge remain, however, among which the three described below are especially important:

**Critical Knowledge Gaps**

**Unhelpful definitions and estimates**

Diverse estimates of the number of slums and the size of the slum population have been produced by government agencies with different views about what constitutes a slum. The Census of India defines a slum as “a compact area of at least 300 population or about 60-70 households of poorly built congested tenements, in unhygienic environment usually with inadequate infrastructure and lacking in proper sanitary and drinking water facilities.” The Ministry of Housing and Urban Poverty Alleviation, following the definition adopted by the National Sample Survey Organization (NSSO), alternatively considers as a slum “a compact settlement with a collection of poorly built tenements mostly of a temporary nature, crowded together usually with inadequate sanitary and drinking water facilities in unhygienic conditions. Such an area, for the purpose of this survey, was considered ‘non-notified slum’ if at least 20 households lived in that area. Areas notified as slums by the respective municipalities, corporations, local bodies or development authorities are treated as ‘notified slums’.”3 Not surprisingly, given these differences in definitions and minimum qualifying size – at least 60-70 households in the Census definition and only 20 households in case of NSSO – and on account of other differences in enumeration techniques, widely varying estimates have been offered. For example, the NSSO and the Ministry of Housing and Urban Poverty Alleviation estimated in 2009 that 16.5 percent of the urban population of
Karnataka lived in slums, but only two years later the Census came up with a figure of 12.2 percent.

Further, official agencies acknowledge only two broad types of slums. There is first a category of officially-declared (“notified” or “recognized”) slums, and then there is a second omnibus category which, by including all other low-income settlements, is hardly ever accurate or complete.4 Vast differences characterize the conditions of life between slums of different types, and these differences are poorly captured by these gross distinctions. Notified slums differ from one another depending upon their age and location. Even larger differences exist within the more unwieldy and unproductive category of non-notified slums. In both definitions, that of the Census and that of the Ministry, there is a common conception that slums are constituted by “poorly built tenements mostly of a temporary nature.” These definitions apply poorly or not at all to many slums settlements, particularly officially notified ones, within many of which it is common to find longstanding multi-storied buildings. There are, of course, other types of slum settlements, closer to the official definition, in which homes are no more than four rickety poles supporting a roof made of rough plastic sheets. But this type of slums is lumped together in official listings with other such non-notified slums, among which many – though hardly all – progress along the path toward permanent buildings.

Little is gained (and much is lost) by considering slums as a homogenous category of settlements or even by sticking to the gross distinction between notified and non-notified types. Constructing better subordinate classifications is necessary for developing more useful and cost-effective policy interventions.

Unknown and unstable boundaries
Even when a slum is notified or recognized by a municipal authority (or identified by census or NSSO enumerators) the spatial boundaries of these settlements are rarely, if ever, plotted on city maps. Slums sprawl over time, stretching their original (unrecorded) boundaries, and new constructions in these spaces remain in legal limbo.5 Other slums, particularly the flimsiest ones, are simultaneously dismantled or relocated. The landscape of slums is ever-changing, but plotting their locations on a map remains still largely a product of guesswork.

No longitudinal information
Resurveys of slum settlements and households to ascertain directions of movement are virtually unknown. Hardly anything is known about whether and how the economic situations of particular settlements and individual households have changed over time. As a result it becomes hard to ascertain whether some particular sets of policies have actually helped or whether a different set of supports will provide more bang for the public buck.6

Each of these concerns is being addressed by a research project that we commenced in 2010 in Bangalore in collaboration with the non-profit agency, Jana Urban Foundation which has for many years provided financial services to low-income populations in Bangalore. It has more recently widened its scope and now provides housing and other social services to these population groups (www.janafoundation.org).
Comparing high-resolution satellite images over a ten-year period, supported by extensive verifications on the ground and detailed household surveys, helped distinguish initially between five types of slums.\(^7\) We present here a comparison between the poorest and best-off slums, discussing the middle categories in less detail, since investigations within these types of slums have only recently commenced.

**Methods: Satellite-Image Analysis verified by Neighborhood and Household Surveys**

Despairing of this poor state of knowledge, particularly about slums locations and boundaries, investigators have turned recently to remote-sensing techniques.\(^8\) Our work in Bangalore extends this trend. We started by relying on Google Earth images compared over a ten-year time horizon to assist with the following objectives.

- Identifying low-income settlements and detecting newly arisen slums
- Tracking changing slum boundaries
- Distinguishing types of slums and constructing a hierarchy of slum types
- Also developing a dynamic typology: in how many different ways have slum settlements moved up the hierarchy (or not)?

Since home addresses within slums, even longstanding ones, are notoriously hard to locate – since both street names and street alignments change frequently – we are additionally

- Geo-referencing entire settlements as well as sample households with the intention of re-visiting them at regular intervals.

The decision to explore Google Earth images was taken after undertaking an initial round of surveys in 2010. These investigations were conducted within 14 slum settlements, selected randomly from among the list of notified slums provided by the Karnataka Slum Development Board (KSDB) after categorizing these settlements in terms of a number of parameters, including number of years in existence, distance from three commercial hubs, poverty ranking as determined by local experts consulted for this purpose, and social and religious composition. Field investigations were carried out by a locally recruited research team, several among whom live within similar slum communities. Every sixth household was selected for interviews, conducted during times of day – early mornings and late evenings – when the chances of finding at least one adult member were the greatest. The team encountered only a handful of refusals. Mostly, an adult female was interviewed (Krishna 2013).

Detailed interviews with 1,481 households living in these 14 notified settlements showed how slums on the official list represent the pinnacle of a vast iceberg, home not so much to the poorest people as to a settled lower-middle class, most of who have lived in Bangalore for multiple generations. This type of slums is furthest from the official definition: permanent constructions prevail; electricity connections and clean drinking water are commonly available. Poverty is low in comparison to the average for the city, with 14 percent of residents reporting incomes below the official line as against the figure for 26 percent estimated for urban Karnataka by the officially-appointed Tendulkar Committee. In terms of assets, as in terms of income and poverty prevalence, notified slum dwellers are located near the middle of the socio-economic spectrum of this city. Kerosene or gas stoves
are owned by nearly every household. Television sets, pressure cookers, and electric fans are the next most common asset types, with more than 80 percent of all slum households reporting ownership. Mobile phones are owned by more than two-thirds of these households. Investment in education ranks alongside home ownership as these households’ highest spending priority. Nearly all children go to schools, with most staying all the way through high school.

But there are also other types of slums in which conditions are “slummier” by degree and people are poorer on average. Blue-polygon slums (discussed below) fulfill all of the conditions specified in the official definition: “poorly built congested tenements…unhygienic environment…inadequate infrastructure…lacking in proper sanitary and drinking water facilities.” Intermediate slum types are progressively better off in relation to one or more of these conditions. But since the worse slum types rarely form part of government records or city maps, they are harder to pin down, far less, investigate.

Hardly anyone living in the best type, notified slums, is newly arrived in Bangalore; the vast majority was born in this city. In no more than 152 households – a little over 10 percent of all interviewed households – is the adult male (or female) a first-generation migrant. A total of 147 households (10 percent) are second-generation Bangalore residents, another 131 (9 percent) are third-generation residents, while the largest proportion, more than 70 percent, have lived in Bangalore for four or more generations.

So where do new migrants go when they come to Bangalore, as so many do year after year? Where do the poorest people in Bangalore live, if not in slums? How any other types of slums are there between blue polygons and notified ones? How does one locate these types of places?

Identifying Slums and Recognizing Slum Types
Since existing data sources are of little help, new and reliable methods of data collection need to be developed. We began our exercise of identifying low-income settlements by drawing the spatial borders of the area administered by the municipal authority, the Bruhat Bangalore Mahanagara Palike (BBMP). This area was divided into four equal-sized quadrants on a map of Bangalore drawn on Google Earth. Considering each quadrant separately helped analyze a more manageable number of identified settlements (polygons), enabling ground verifications to be made quadrant-by-quadrant.

We found that examining images at an altitude of 4,000 feet was most helpful for our purposes, and we compared settlements at the same height level on Google Earth. Google Earth’s time range of data varies. For most settlements, there are satellite images starting in 2000. However, some only have images dating back to 2002 or 2004. Similarly, the vast majority has an updated 2011 image, but some only some have images dating to 2010. In order to generate comparable data, the first year with a satellite image was referred to as the “initial year” and the most recent year with a satellite image is referred to as the “final year,” allowing us to measure average changes per year in settlement size, housing stock quality, and housing density. We also analyzed satellite images for several intermediate years, as Figure 1 shows, which enabled us to commence the task of identifying settlements’ trajectories over time.
After several iterations between satellite-image identification and detailed verification on the ground, we were able to shortlist a first list of criteria. Based on the following initial identification criteria, 279 low-income polygons of different types were identified at the start:

- lack of space between shelter units;\textsuperscript{11}
- roofs that appeared to be low-quality based on brown or weathered grey coloring;
- a hodgepodge pattern of shelter units;
- lack of proper roads (if there are roads, they are brown, narrow and unpaved);
- lack of shadows adjoining the shelter units, signifying that they are low to the ground, thus not multi-storied.

A unique name was provided to each such polygon based on the nearest named neighborhood or water body. Iterative ground verification exercises led to continuous improvement in our ability to accurately delineate low-income settlements of different types and to exclude better-off communities (including notified slums).

Successive iterations helped classify the slums we had studied into distinct types. On-the-ground verifications of a total of 193 low-income settlements helped us classify them into the following types and subtypes: (Box 1)

Figures 2 through 7 provide illustrations of the different types, highlighting some visible differences. The quality of the homes and of the infrastructure drops as we go down the hierarchy of slums depicted in Box 1.

The lowest-income category of settlements are the blue polygons. Such settlements were identified based on our initial rounds of field visits, when we understood that new settlers live mostly in temporary settlements and that the color of these roofs is rarely grey or brown. Homes within these newer settlements are in general covered by blue plastic sheets (referred to as tarpaulins, but made of plastic based material). The recurrent observations that temporary settlements tend to have blue-colored roofs provided us with a different set of criteria for identifying the poorest settlements. In exploring these settlements, we used the time slider feature on Google Earth and began noticing that these settlements had come up in the most part within the past few years, although some have been around for much longer, growing in size over the ten-year period observed. The ground-verified criteria that we used for identifying subsequent blue-polygon settlements on satellite images are the following:

- small shelter unit size
- blue roofs
- established or expanded recently

Figures 8 and 9 show two additional examples of settlements of this type, also indicating how these settlements were identified. The comparisons presented of before-and-after satellite images provide indication of the rapid pace of transformation that is bringing into existence ever-growing numbers of this type.

We identified 61 such settlements in all, and our ground-verification exercises showed how these initial identifications were accurate in the vast majority of cases. A total of 8 settlements among the 61 identified on satellite images no longer exist, either because they have relocated or because of an error in identification. It is also likely that some newer settlements have come into being, which we were unable to identify because of satellite image data that do not go beyond 2010. Thus, while our methodology is subject to the error of omission – not picking up recently established blue polygons – errors of commission are minimal; no false positives were revealed in our ground verification exercises.

In all, therefore, four distinct types of slum settlements have been identified through this process of analysis. Each of these four types (and subtypes) is different in important respects from other types.

In the rest of this paper, we present a comparison between the two slum types that represent the extremes of this hierarchy – first-generation settlements (blue polygons) and fourth-generation slums, the notified list of KSDB. Since detailed field surveys including household interviews have only recently been commenced in the other types and subtypes, we have little further to say in this paper about these slums, except to remark that the
distinctions detected between them have proved robust in initial field verifications and neighborhood surveys.

Blue-Polygon Slums
The lowest type of slums – blue polygons – are first-generation both in terms of being newly established and in relation to the duration of residents’ association with Bangalore. They are home to recent migrants from rural areas, mostly from northern Karnataka and the adjoining state of Andhra Pradesh, although a few have come from as far away as West Bengal and Uttar Pradesh. These slum residents retain strong links with their native villages, going back and forth often, with many families split between the two locations. The development of this type of slum is in considerable part a response to diminished and uncertain rural livelihoods. Reasons for coming to the city are implicated primarily in agrarian crises brought on by droughts and erratic rainfall and the consequent need to pay off accumulated debts.

The typical abode is a 7’x7’ tent erected on land hired from a private owner. Families of between 3 and 5 individuals share these meager spaces, with a large majority of adults (male and female) and many older children employed as construction labor. Indeed, some among these settlements are construction sites, while some others, pending the grant of building permits, instead of lying vacant, have been let out temporarily to migrants, earning rent for their owners. Occupants pay rent for every month they are allowed to remain, never knowing when they might be evicted. The monthly rental figure for one of these tiny plots ranges from Rs. 200-400, with migrants from more distant regions paying higher amounts, particularly if their group is small in number. These amounts are paid in cash and “under the table; there are no receipts and certainly no written leases.

We undertook detailed investigations in a randomly selected sample of 18 first-generation settlements of this type between August and December 2012, conducting interviews with a total of 631 households, a little more than half of all households then living within these settlements. We selected households for interviews following a process of random selection (picking every second household starting from a common point), although in a few cases these protocols were breached, since contact with some households proved impossible despite repeat visits. Residents tended to be suspicious of outsiders. Appeals to local leaders or the owners of these lands were often necessary in order to gain entry. But once the initial doubts were allayed, interviews proceeded with ease. There were hardly any refusals.

On average, 70 households – most having migrated from the same rural village or adjoining group of villages – constitute a first-generation settlement, with settlement sizes ranging from 10 to 150 households. About 40 percent of households came to Bangalore between one and five years ago, and another 40 percent have been in this city for between five and ten years, with a smaller proportion, about 15 percent, having stayed in Bangalore for more than ten years.

Prior to coming to the city the principal occupation of a little more than one-half, 52 percent, of residents was agricultural labor. Another 40 percent farmed small plots of land, supplementing these incomes with farm or off-farm labor. While primarily agrarian in origin, as many as 38 percent of these households own no agricultural land of their own, another 34
percent own tiny plots of between one and three acres, with only 7 percent owning five or more acres of agricultural land.

Notably, a large majority of these residents, 72 percent, belong to Scheduled Castes (SCs), the former untouchables – more than three times the share of this group in the population of Bangalore. Scheduled Tribes (STs), India’s aborigines, constitute another 11 percent. Other Backward Castes (OBCs) make up 7 percent of this group. In 8 of the 18 selected neighborhoods, SCs constitute 100 percent of the settler group. Table 1 provides these details for all 18 neighborhoods.

Table 1 about here

Their caste backgrounds, land holdings, and prior occupations show how this group of households comes from among some of the poorest people in rural India, impelled to move from their native villages by the diminishing economic prospects that have been brought on, in the longer term, by fragmenting landholdings, and in the immediate term by debts and droughts and climate changes. More than 80 percent cited droughts, debts, and the general difficulty of making a living in their native villages as their principal reason for making the trek to the city. These impressions are strengthened when one considers other aspects of lifestyle including current occupations and asset holdings. Men and women work on construction sites as irregular, daily-waged, labor, with men earning, on average, Rs. 300 for each day’s work, and women, earning lower amounts, around Rs. 200, even when they do the same kinds of work.

Few possessions are visible within these 7’x7’ tent dwellings: shabby clothes strewn about or stored on wooden planks that are balanced atop brick or earthen supports; three or four battered aluminum cooking vessels; an open wood-burning chulha (fireplace); a mobile phone to stay connected with the family in the village; pictures of Hindu gods and goddesses; and one or two plastic containers in which water, brought from afar, is stored.

Blue-polygon settlements are mostly unconnected to city services, and they are poorly connected as well to sources of economic opportunity and social mobility prospects. None of these 18 settlements is connected to the electricity network. Not one is served by street lights. Darkness after sunset, combined with muddy, narrow, twisting and unpaved alleyways and the frequent presence of vicious bands of stray dogs, made it imperative to complete household interviews early, immediately after householders returned from a day of work. A hand-pump in one neighborhood and a bore-well in another neighborhood serve as the exceptions; residents of the remaining 16 neighborhoods purchase the water they consume from mobile tankers or they travel great distances to fill up at public water points. Garbage removal and security services are unknown. The nearest public bus stop is located within one kilometer of only two settlements and it is more than three kilometers from another nine settlements. The nearest health clinic, government or private, is four kilometers distant, on average. There are no signs visible in any neighborhood of ongoing government, NGO or other outside supports.

People here are generally left to cope on their own. They rely only upon immediately family or neighbors for support. Our interviews revealed how in dealing with a variety of situations, of both an everyday and an emergency nature, only a tiny percentage has been
able to call upon support from employers, community leaders, government officials, political parties, NGOs, or any other organized force.

Prospects for advancement and permanence are severely compromised on account of frequent absences, occasioned by visits two or three times a year to the native village. Such visits are necessary to look after the land and family left behind and to service the debts that originally brought one to Bangalore. Only 32 of 631 households (5 percent) did not visit their native villages even once during the 12 months preceding this survey. Another 157 households made one visit, 229 households made two visits, and the remaining 213 households made three or more visits to their native village in the year preceding these interviews. On average, 2.3 trips were made annually, with a total period of 32 days being spent in the native village. A great deal of expense was incurred on these visits as well as on monthly debt repayments. As many as 494 households, 80 percent of the total, have one or more debts outstanding in their home village. The average outstanding debt is Rs.116,800 – on which interest is added at rates ranging between two and four percent monthly. More than two-thirds of all loans have been contracted from moneylenders, with about one-quarter coming from family and friends.

Repeatedly, these people informed us how they have come to the city with the main purpose of repaying the debts that their families and they have accumulated back in the village. Whatever they are able to save from what they make working as construction labor (the principal occupation of more than 80 percent of all male and female household heads) or as casual labor of other kinds goes into building a better life back in the village. Thus, opportunities for self-improvement in the city are passed by; they are neither actively pursued nor often even visualized as real possibilities.

Table 2 shows the distribution of average monthly expenditures for these blue-polygon households. More than one-quarter of this total goes toward meeting obligations connected with the native village, with 16 percent going toward debt repayment and another 12 percent toward travel and remittances. The average household sends to its native village a sum of Rs. 1,840 every month.

- Table 2 about here -

Notice in Table 2 how only a tiny proportion of the household budget, 4.8 percent, is spent on education. In fact, no more than 21 percent of all 631 households spends any amount whatsoever on tuition, fees, and other school-related expenditures. Very few children are sent to school.

- Table 3 about here -

Table 3 shows the distribution of educational attainment by age and gender. Access to education does seem to be improving, but only very slowly, even as the education “threshold” – the point at which the educational qualification makes a significant difference to one’s earning potential – has been rising simultaneously in India14

More than three-quarters (77 percent) of all household members aged 14 years or older have no formal education, having never been to school. More young people of school-
going ages are out of school than attend schools regularly, and those who do attend school do so sporadically, dropping out for the most part after attending for only a couple of years. Those few young people who do attend schools regularly are the ones who have remained behind in the native villages. Partly as a consequence, the vast majority of education is conducted in local languages, with 75 percent and 16 percent, respectively, attending Kannada-medium schools and Telugu-medium schools. No more than 4 percent attend English-medium schools, an important point of difference with notified slums, in which the vast majority of young people attend regularly through high school, with more than 60 percent being given an English-medium education, the better to raise career prospects. The itinerant life that is lived by residents of blue-polygon slums along with their economic difficulties makes it hard for them to keep children at school.

Lack of official identity papers acts as a further deterrent. The papers that blue-polygon residents possess are related to their residence in their native village. Only a tiny proportion is registered in any way as a resident of Bangalore. Thus, 69 percent have a Voter ID card in their native village, but fewer than 9 percent are registered to vote in Bangalore. Similarly, 65 percent have a ration card issued in their native village, but only 6 percent have one in Bangalore. The corresponding proportions for a Unique ID (or Aadhar) card are 17 percent and 1 percent.

Not only getting children admitted to school, but also availing themselves of any other social services or benefits in the city, becomes virtually impossible in situations where people’s very existence is not recognized or registered by the city. The comparable situation in notified slums is very different, as we will see in the next section. Cut off from flows of social assistance as also flows of information and influence, blue-polygon residents eke out a meager living, surviving from day-to-day but hardly making any considerable progress from year to year.

Intergenerational occupational mobility is virtually non-existent. Principal occupations among current male heads of households are very much the same as they were for their fathers and grandfathers, the vast majority of who also hired themselves out as casual labor. The only difference is that while fathers and especially grandfathers scratched out a living by working as agricultural and coolie (plantation) labor in rural areas, current-day adults in blue-polygon slums work as casual construction laborers in Bangalore.

The small advances that they are able to make are quite often compromised by adverse events. Exposed to risk in two places – in their city tents as well as in their native villages – the lives of first-generation slum residents are doubly precarious. Along with droughts and rainfall failures, remarked upon earlier, deaths, marriages and health incidents combine to eat deeply into these households’ meager savings, making further debt necessary in the majority of cases. A total of 447 households (71 percent) reported experiencing a health incident requiring substantial expenditure (of Rs. 30,285, on average) during the preceding year. Expenses on marriages added more than Rs. 100,000 over the prior five years to the outstanding debts of 391 households (62 percent).

Their livelihood patterns in the city, coupled with meager or non-existent policy supports, instead of enhancing resilience, place a low upper limit upon these people’s capacities. The threat of eviction is ever present. And yet, lacking alternatives, some among
these shabby and easily dismantled settlements have been in place for ten years or longer, with the average age of settlements being a little more than 6.5 years.

**Comparing Slum Types: Best and Worst**

In contrast, notified slums represent, in general, a higher order of livelihood, not merely surviving from day-to-day but building assets and investing in education and skills – with many becoming a part of a lower middle class, a result of incremental gains won over multiple generations through a series of political gains and official accommodations. As mentioned above, these settlements have been in existence for long periods of time, and the vast majority of residents trace their associations with Bangalore over multiple generations.

Diverse points of comparison – asset holdings, occupation types, aspirations and investments in children’s education, identity cards, cooking needs, vulnerability to natural disasters, etc. – make clear how first-generation migrants settled in blue-polygon areas constitute a very different population group compared to fourth-generation notified slum residents. Analyzing separately their compulsions and prospects helps make for a more nuanced and thus more effective slum policy.

In one respect, however, being in a slum, no matter of what type, has a similar rather than a different consequence. In the most part, slum residents, while living in the city, are only poorly connected to the kinds of institutions that make the city a source of economic dynamism for other population groups. Lack of information and lack of connection are common themes across diverse types of slum settlements. In other respects, however, understanding the differences that exist across diverse types of slums, and coming to grips with the sources of these differences, is helpful for policy formulation.

**Assets**

A household’s asset holdings provide one indication of its ability to withstand shocks without succumbing to poverty. Comparing the asset holdings of these 631 first-generation (blue polygon) slum dwellers with those of 1,011 fourth-generation residents (more than 70 percent of all residents interviewed in notified slums in 2010) provides one measure of the gulf separating these two types of slum.15

Hardly any fourth-generation resident of notified slums in Bangalore has any ongoing relation, economic or social, with a rural village. Their asset holdings like their sources of livelihoods are entirely contained within Bangalore. In contrast, first-generation blue-polygon residents divide their times and often also their families between the city and the native village. Table 4 reflects these divided livelihoods, considering, first, the asset holdings of blue-polygon resident in the city and then considering their combined assets in the city and the native village.

- Table 4 about here -

Notice how the asset holdings of fourth-generation slum residents dwarf those of first-generation migrants. More than 80 percent of fourth-generation residents possess
televisions, electric fans and pressure cookers. The comparable percentages within the blue-polygon settlements are no larger than 1 percent in each case (with somewhat higher percentages prevailing if we were to consider combined asset holdings in the city as well as in the native village).

Different classes of people reside in these two types of slums. Considering home ownership in addition to these other assets further reinforces this impression. As many as 52 percent of fourth-generation residents own the homes in which they live, with most of them (85 percent) titles to the land and building. In contrast, not one blue-polygon resident owns a home in the city.

Asset building among notified slum dwellers, occurring incrementally, takes the form of acquiring first a home and the basic necessities, such as gas or kerosene stoves, pressure cookers, and electric fans. Interestingly, TVs are also acquired early in the process of asset acquisition. Apart from its entertainment value, television also serves as the primary source of information. Nearly 90 percent of notified slum residents rely upon television for their information needs.

Mobile phones – essential for keeping up with one’s customers, employers, and suppliers, and in the case of blue-polygon residents, also with families back in the native village – are also acquired early on by slum residents of all kinds. In this respect, a mobile phone is a very special kind of asset, whose possession is only loosely related to overall economic status. The cheapest available sets, with prepaid plans, predominate, especially with blue-polygon settlements.

One other big difference in assets, particularly related to environmental impacts, concerns the nature of domestic fuels used by first- and fourth-generation slum households. While nearly all fourth-generation households rely upon cooking gas or kerosene, all but one or two blue-polygon households collect or buy firewood for their cooking needs.

**Occupation Types**

What people do – and what their circumstances and backgrounds prepare them for doing – influence what they can accomplish by way of building assets and acquiring skills. A key point of difference between fourth- and first-generation residents relates to the places they occupy in the city’s economy. Table 5 brings out differences in the distribution of occupation types.

- Table 5 about here -

While first-generation residents work predominantly as casual labor in building construction, fourth-generation residents are distributed across a variety of occupations, with the largest share engaged as skilled and semi-skilled tradespeople, carpenters, electricians, and suchlike. Another large chunk of fourth-generation slum residents is employed as office clerks or security guards. Fewer than ten percent are employed in construction activities, constituting the lowest-paid and least secure part of the occupational spectrum.

Differences in female occupation (not reported in a separate table for want of space) reflect the differences seen above in the case of males, with the majority of blue-polygon females, 62 percent, being employed as casual construction labor or helpers in building
activities, and only 12 percent of fourth-generation females being employed in similar trades. Younger fourth-generation females have made considerable gains compared to their mothers and grandmothers. After completing high school, they have gone on to work as shop assistants, call-center operators, and secretaries in offices. Education has served thus as a pathway to social mobility, albeit still of a limited kind. No notified-slum dweller in our sample of more than one-thousand has become a medical doctor, lawyer, senior government official, or MBA – and no young person is currently attending the kinds of educational programs that can prepare them for such careers.

Informal occupations predominate in both types of slums, but earning potentials are vastly different. People’s abilities to invest in their children’s futures are also considerably different.

**Education and Aspirations**

Notified-slum residents invest heavily in education and in the acquisition by their children of additional skills, particularly, English and computer knowledge. All but a very few children of school-going age attend schools regularly, girls as well as boys, going all the way up to and including high school. Boys usually get between ten and 15 years of formal education, with the median figure being 12 years. Girls, on the other hand, study on average for two fewer years, generally finishing school after 10 years of formal education. In contrast, the majority of school-age children in blue-polygon slums are out of school, and only a small minority get educated all the way to high school, and then, too, in schools where the medium of instruction is Kannada or Telugu.

Awareness of superior career possibilities is high among residents of notified slums, far higher than among residents of blue-polygon slums, the majority of whom were unable to state any particular career aspiration for their daughters and sons, and those who did state something definite in response to their question, mostly cited something vague and all-encompassing, such as “acquiring education” or “getting a job.”

In consequence, social mobility is virtually non-existent among residents of blue-polygon slums. Sons and daughters have followed mothers and fathers into the same kinds of low-skilled, low-paid, and precarious occupations, working in the village as agricultural labor and in the city as construction labor with no secure or reliable perch.

**Degrees of Informality**

Slum types can also be distinguished by the extent to which informality is implicated with residents’ lives. Three sources of informality are separately important affecting, respectively, jobs, homes and people. The first source of informality, related to jobs, is commonly experienced across all types of slums. Given that workers with formal jobs constitute less than 10 percent of the Indian workforce, and the remaining 90-plus percent are informally employed, it is hardly surprising that all but a very few slum dwellers’ experience informality in the workplace.

The second and third sources of informality are, however, very differently distributed across types of slums. Homes without titles are the norm in blue-polygon slums: none among the blue-polygon settlers we surveyed had title to the home (if indeed four poles and a blue polygon can be properly regarded as a title-able home) or to the land upon which it
stood. In notified slums, however, the majority of residents have titles to the land or the
house or both. The situation in intermediate slums lies between these extremes.

In blue-polygon slums, even the people are informal. Lacking identity papers in
Bangalore, they are non-people in the eyes of planners and political entrepreneurs.
Characterized by sociologist Jan Breman as “nowhere people” – those who have no firm
foothold, neither in city nor village, but who must move between both merely in order to
make ends meet – tens of millions of village residents go to cities for short periods at a time,
returning to their village homes for the remaining part of the year. Such people are typically
missed out in official counts and academic studies. In contrast, in notified slums, very few
are without identity papers, particularly voter registration cards, and are thereby able to enter
into bargains of services-and-recognition for votes.

A rough informality index can be constructed by giving a value of zero or one to each
of these three sources: jobs, homes, and people. Each individual’s score can range from a
minimum value of zero to a maximum value of three. Slum types can be distinguished by
their average informality scores. The lowest scores will be found in the most developed
slums, the notified ones, falling regularly through the hierarchy, and being lowest in blue-
polygon slums.

Sources of Institutional Support
Mitlin and Satterthwaite assert how “those living in informal settlements have no influence
on local government or service providers, who ignore them and their needs.” Their
depiction adequately characterizes blue-polygon settlements and it applies in some part also
to notified slums.

Not one blue-polygon resident has benefited from a job training or skill development
program run by any government agency or NGO. Even in notified slums, fewer than ten
percent of all currently employed fourth-generation residents were able to avail themselves
of any vocational training or skills building programs, with the rest, more than 90 percent,
learning the trades they practice through informal apprenticeships taken up with parents,
relatives or friends. Information about career alternatives is obtained through word-of-
mouth; no employment exchanges or career counselors are at hand.

Migrants when they first come into the city are rarely served by any government
agency, or for that matter, any NGO. Those who obtained assistance did so in the most part
from friends and relatives. When preparing for retirement and old age, 99 percent of slum
dwellers expect to rely only upon immediate family, relatives, and friends. Less than one
percent expected to receive any help from any government agency or NGO.

Slum dwellers do not actively wish to remain aloof from public institutions; that is
not an explanation which this body of evidence supports. Given a choice, the largest number
of slum residents want to engage actively with public institutions, also obtaining from them
assistance and advice of different kinds. They want better schools, educational and housing
loans on reasonable terms, vocational training, career guidance, and infrastructure
improvements. But very few have actually received assistance in any of these forms. We
asked a number of questions about the nature of connections they have made or which they
would wish to make with government and non-government agencies. In each case their
responses were strongly suggestive of impoverished networks and weak institutional connections.

People rely for the most part upon their individual social networks, but these networks are poorly endowed with resources and connections. In terms of helping facilitate connections with people who have any real influence – such as doctors, lawyers, elected officials, newspaper reporters, policemen, and factory owners – these existing social networks have very little value. We asked our respondents about whether they felt they would be able to connect with any of these (and other) people with influence. As many as 70 percent in notified slums and 95 percent in blue-polygon settlements mentioned that they would not be able to connect with even one individual of these different types.

Their social networks, the individuals whom they can consult on a regular basis – relatives, friends, and neighbors – provide them with all the job-related knowledge and professional connections that they are generally able to muster. Preliminary investigations in the intermediate-types of slums are also revealing how obtaining public infrastructure and services has been conditioned upon the strength of local social and political networks. In these and other cases, formal institutions have not stood in support of individuals’ and communities’ goals. Studies conducted in other slum settlements, in India and elsewhere, show how this situation may not be peculiar to Bangalore.  

Conclusion
The population of urban slums has been expanding rapidly in India. Two separate processes, with different internal dynamics and consequently diverse repercussions for policy, have contributed to this growth.

One part of the increase has come about through natural processes: births occurring within slums, outpacing deaths, have resulted in a natural process of population growth. This process is most prevalent within longer-established slums, and it was particularly visible in our surveys of notified slums, where the majority of residents, more than 85 percent, born within slums, have continued living there, incrementally building better lives and adding to asset holdings.

But there is also a separate process that is adding to slum populations, which is playing out more often at the lower end of the spectrum of slums. It is bringing first-generation migrants into the newest and flimsiest settlements, where poverty, uncertainty, risk, and vulnerability are more centrally implicated in people’s lives and livelihoods, and where resilience is much lower in comparison to notified slums. Longer-term diminution of economic prospects in agriculture coupled with the lure of growing cities has contributed to this process but so, too, have factors associated with changing climatic conditions. The largest proportion (81 percent) of our blue-polygon interviewees stated that their principal reason for coming to Bangalore was related to the increasing frequency of rainfall failures resulting in droughts, difficult working conditions in the village, and accumulating debts. As climate impacts add further to the precariousness of rural livelihoods, more such settlements can be expected to be given rise.

Currently organized helter-skelter, wherever niches are temporarily available, the kinds of settlements that currently serve as home in Bangalore to new migrants from distressed villages hardly serve as locations for building a better life. Such people live within
a narrow cocoon formed by fellow settlers and migrants whose lives are equally devoid of prospects for substantial improvement. They have no papers in Bangalore and no fixity of tenure – these settlements have not appeared on local political entrepreneurs’ radar screens, either because they stand no chance of getting legal rights, are itinerant, or small in number – and residents are liable to be evicted, as many of our interviewees have been, with very little notice. Given these circumstances, these families aim not so much to build a better life within Bangalore as to use Bangalore as a means for paying off the debts that they have contracted in their native village. Children’s education is given short shrift in the face of other more compelling and immediate commitments. Home improvements are neither feasible given that there is little left over after sending money back to the village, nor are such improvements desirable in situations where the threat of eviction is ever-present.

These situations contrast starkly with those experienced by native-born Bangalorians living in notified slums. Home ownership and children’s education are the two highest priorities of people living in these other kinds of slums. There is no real threat of eviction for these residents, and the need to send remittances to other places is also non-existent for all but a very few.

Preliminary investigations in the intermediate-types of slums are showing how differences across types – while not as stark as those between notified and blue-polygon slums, the two bookends – are nevertheless significant enough to warrant separate treatments. Needs and contexts vary across types of slums, both in terms of current lifestyles and future expectations.

As a consequence, diverse kinds of policy supports are required by people in the separate types of slums. Going by what we have observed about the two bookend types, notified-slum residents will benefit most from receiving supports that can help raise social mobility, enabling their children to become, not only security guards and shop assistants, as so many have, but also to become medical doctors, software engineers, senior business professionals, and the like, positions not so far achieved by any but a tiny few. Notified-slum households are investing heavily in education, but the returns on these investments are currently low.

In contrast, blue-polygon settlers have a very different set of expressed needs and hopes regarding public assistance. Their basic needs – electricity, clean drinking water, security of person and property, education, secure housing, affordable health care – are largely unmet or require large expenditures. Lacking identity papers in the city (and not registered as constituents or voters), blue-polygon dwellers have not been able to attract much political patronage or official support. Drives to acknowledge and register their presence in the city will, therefore, have to take precedence. Researchers who have intensively studied one such settlement in Mumbai, focusing primarily on health outcomes, underline how this type of slums constitutes a “legal ‘no-man’s land’ – a zone absent of policies that address their existence as human beings and citizens of the city,” and they “emphasize the need to establish minimum humanitarian standards for …basic services such as water, sanitation, solid waste collection and restitution after calamities.”

So far mostly lacking, the effort to develop complete slums maps – with clearly marked boundaries and with settlements classified in terms of a clearer typology – must also be taken forward vigorously. Relatively little is known about how slums develop and how
and when (and if) they make the transition from blue polygon to notified status. Our ongoing enquires show that there is a whole spectrum of settlements, ranging from blue polygons to long-notified ones. In some cases, “incremental house improvements have transformed huts into dwellings made of durable materials,” but not all homes and not all settlements are able to move from one end of the spectrum to the other end; many are unable to cross past crucial transition points. What barriers exist at each transition point which some but not other settlements are able to get beyond also needs to become better known.

The methods presented here represent a useful starting point for undertaking similar inquiries in other cities. They have proved productive in Bangalore, but how far they will be useful, with and without modifications, in other large and small Indian cities needs to be investigated separately, something we intend doing in the near future. We hope that our ongoing research will develop a finer typology of slums, also uncovering critical transition points and patterns of movements over time.

NOTES

1 The practice of enumerating slum populations was commenced in the preceding census (of 2001), but this earlier exercise was confined only to considering slums located within the largest Indian cities.

4 We use interchangeably the terms “slum” and “low-income settlement.” Official documents usually utilize the former term, while academic discourse is divided on appropriate usage. For a more detailed discussion on terminology, see Roy, Manoj, David Hulme, and Ferdous Jahan. (2013). “Contrasting Adaptation Responses by Squatters and Low-Income Tenants in Khulna, Bangladesh.” Environment and Urbanization, 25 (1): 157-76. esp. footnote 1.

5 See Joshi, Pratima, Sen, Srinanda, and Jane Hobson. (2002). “Experiences with Surveying and Mapping Pune and Sangli Slums on a Geographic Information System.” Environment and Urbanization, 14 (2): 225-40. The authors provide an example from the Indian city of Pune of a slum settlement that has doubled in size after its boundaries were initially recorded. “The result,” they suggest, “is settlements where certain areas have some provision for [municipal] services whilst others are completely un-serviced,” making for an untenable situation in practice.

7 The initial breakthroughs on developing this satellite-image based methodology of slum identification were made by Andrew Leon Hanna and Grady Lenkin, students from Duke University, and Rui Shan Foo of the Singapore Management University, each of whom spent several weeks in Bangalore.

9 Rather than considering what is colloquially known as Greater Bangalore (which extends over a wider and fast-expanding area, covering in addition to the BBMP's jurisdiction several smaller peri-urban areas), we selected to focus initially on a well-identified area constituting the core of this city. Our methodology can be extended to Greater Bangalore at a later stage

10 These quadrants were numbered going counter-clockwise starting from the northeast and using the "ruler" feature of Google Earth to find the midpoints of each line segment and the "line" feature to draw the quadrant boundaries.
We refer to “shelter units” instead of houses because there is no way of determining based on Google Earth satellite images how many housing units are included within a visible shelter unit.

While plastic sheets similar to the blue roofing sheets are available in multiple colors, blue sheets are the least expensive and most commonly available, thus most extensively used.

It should be useful to examine how many migrants have returned to their villages after repaying the debts that originally brought them to the city. From what we learned during our visits, we feel that the proportion is low, but we are unable to confirm these impressions – since we interviewed only those still living in the city (and none in a village).

Household and neighborhood schedules used for the earlier survey in notified slums are nearly identical to the ones used later for the blue-polygons surveys.

See, especially, NCEUS (2007; 2009), but also, Dougherty (2008); Kannan and Raveendran (2009); and Unni and Raveendran (2007).

Summarizing his evidence, Mitra (2006: 2126) concludes that “in accessing the present occupations informal networks or contacts operating through relatives and other kinship bonds have played a major role… Apart from immediate relatives no other source of contact appears to be of any significance.” Less than two percent of slum dwellers were assisted in their job search by any NGO, and less than one percent took help from a private consultant. Non-institutional means of gaining information and access were utilized by more than 95 percent. Studying slum communities in Dhaka, the capital city of Bangladesh, Banks, Nicola. (2008). “A tale of two wards: political participation and the urban poor in Dhaka city.” Environment and Urbanization, 20 (20). found similarly how social networks can matter more than level of education.
